ARCHAIC CLAY FIGURE OF A SHAMAN 'A MASTER OF PRESCRIPTIONS —Shamanism is found in many parts of the earth among peoples practising a primitive religion of polytheism and polydemonism and conspicuously among Mongolian tribes It probably reached China in he earliest times through the Mongol Tartars The Shaman exercised a dual function He was both priest and medicine man the latter role more often predominating His methods consisted partly in the performance of magico religious rites—in which by reason of his relations with the spirits he was able to cajole or threaten and ultimately drive out the demon whose presence in the patient caused disease—and partly in the application of a rough empirical knowledge of crude surgery and of remedies such as herbal concoctions sweat baths etc The whole proce s was accompanied by wild ecstatic behaviour on the part of the Shaman who also made as much noise as he possibly could with drums rattles and other instruments The Shaman in spite of the crudity of his methods is entitled to be considered a pioneer in the art and science of medicine. According to Chinese tradition miniature clay models of Shamans were buried with the dead in Chou times and the inference is that as the Shaman cured disease and warded off pestilence during life he would through his image continue to perform the same service for the departed The name of the Chou exorcists—the Fang Siang Shi—appears to be built up thus Fang shi a master of prescriptions and Siang to judge of by looks Down to quite recent times diagnosis among the Chinese has been a very rough and ready process the "look of the patient being one of the physician s chief guides

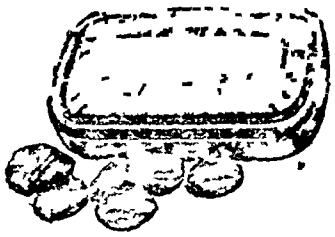
The 'Allenburys' PASTILLES

Glycerine and Black Currant Pastilles

Delicate in flavour *Efficient in use*

They are manufactured from pure glycerine and the fresh juice of choice ripe black currants by a special process which conserves the full value and flavour of the fruit The 'Allenburys' Glycerine and Black Currant Pastilles have a demulcent and mildly astringent effect, most useful in allaying simple irritations of the throat They dissolve slowly and uniformly, and have a *delicious and slightly acidulous flavour.*



Supplied in metal boxes containing 2 ozs 4 ozs., 8 ozs and 1 lb respectively.

The 'Allenburys' Medicated Pastilles

may be relied upon to present the accurate amounts of the active ingredients and to be thoroughly effective in use They dissolve slowly and uniformly, ensuring a thorough suffusion of the medicament over the mucous membrane 81 varieties of the 'Allenburys' Medicated Pastilles are manufactured

Descriptive Booklet and Price List sent on request to members of the Medical Profession

Packed in original tin boxes containing 3 ozs 8 ozs, and 1 lb respectively

on

TUBERCULOSIS OF THE LARYNX:

ITS SIGNIFICANCE TO THE PHYSICIAN

Delivered before the Royal College of Physicians of London, November 6th, 1924,

by

Sir Sclair Thomson, M.D.

It would not be an exaggeration to say that to-day in England and Wales, there are 106,990 individuals afflicted with tuberculosis of the larynx. This figure is arrived at in the following manner. In the year 1923 the deaths from pulmonary tuberculosis amounted to 32,097.* Now, statisticians are of opinion that for every single case which succumbs during a year there are ten others still suffering from it, this gives us 320,970 as the number of consumptive invalids in one year. Of these 320,970 patients the proportion who must have a laryngeal complication is at least one in three, and so we arrive at 106,990 as a modest estimate of the number of those who, in this country to-day, require relief or cure for tuberculosis of the larynx.

Of every ten persons born one is going to die of tuberculosis, and as a rule he will succumb while in the prime of life. Tuberculosis is the most important disease with which humanity has to cope. There is no other specific disease so common in the larynx. As the 106,990 cases in this country to-day must look principally to the physician for guidance and help, it is well worth while considering what assistance in his task can be offered by a laryngologist who, during a period of ten years, has carefully watched the progress of 477 instances of laryngeal disease, in 2,541 patients with pulmonary tuberculosis.[1]

Proportion of Laryngeal Cases in Pulmonary Tuberculosis

In the early years of this investigation one case out of every four had trouble in the larynx, while the average of the whole decade showed a proportion of 18·77 per cent. These patients were seen in a sanatorium and were relatively early cases, for the records of the *post mortem* room show that the larynx is diseased in 48 to 83 per cent. of all fatal cases.

Suggestive Symptoms.—The physician would therefore be well advised to be prepared to encounter a laryngeal lesion in a considerable number of his consumptive patients. The importance of this recognition will be brought out later on. The two most suggestive symptoms to him will be—first, slight but persistent hoarseness and secondly, discomfort referred to the throat or even pain in swallowing. The latter is a symptom which is more frequent with advanced cases, therefore for the all important attainment of an early diagnosis, any hoarseness or any slight change in voice which does not clear up in two or three weeks should rouse suspicion and entail an expert examination of the larynx.

Without Change of Voice.—But we must not forget that tubercle occasionally invades the larynx without causing the slightest alteration of voice or any other local symptom. This is quite understandable if we remember that disease may be deposited in the epiglottis on a ventricular band or on the arvepiglottic fold without interfering with the glottis or impeding the clear vibration of the vocal cords. Of the 477 cases of laryngeal tuberculosis I found no less than 57 (34 men and 23 women) who had no complaint of their throat, and whose voices—both to their own ear and to mine—sounded quite clear and normal. The regular physician should therefore be prepared for the possibility of a laryngeal lesion with his consumptive patients even when they have a clear voice. The proportion is small, my 57 cases occurred in 2,541 patients—an average of only 2·2 per cent., still an examination of a patient with pulmonary tuberculosis—or even suspected of it—cannot be regarded as complete without a laryngeal inspection.

Proportion of Laryngeal Cases in Relation to Sex

Since the days when change could be diagnosed in the larynx by the aid of the laryngoscope (invented by Manuel Garcia in 1854) it has been accepted that men are more prone to develop laryngeal tuberculosis than women just as the male larynx is regarded as more disposed than the female to be attacked with any disease. It used even to be thought that the female sex was less subject than the male to contract pulmonary tuberculosis. But it has been shown that any difference between the sexes in this respect is *not*, as regards tubercle due to any sexual predisposition, but simply to the fact that, until recent times, women have led a more sheltered life and have been less exposed both to fatigue and to infection than men who work in office or factory. When both sexes are exposed to the same conditions woman is just as subject to tuberculosis (in lungs or in larynx) as man—perhaps more so. A glance at Fig. 1 will show that the difference of laryngeal disease in the two sexes is so slight that it may be disregarded. The conclusion is that, amongst bread-winners, we must be prepared to find tubercle just as frequently in the larynx of the female as of the male. Another conclusion is that man's greater indulgence in alcohol and tobacco does not seem to render his larynx more vulnerable to tuberculosis.

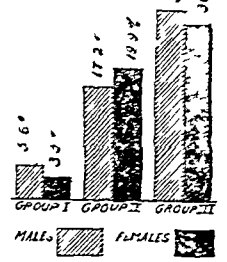

Fig. 1.—Percentage incidence of laryngeal cases in the two sexes and in the three stages of pulmonary tuberculosis.

Proportion of Laryngeal Cases in Relation to Stage of Pulmonary Disease

It has long been established that the frequency with which the larynx is invaded increases with the progress of the pulmonary disease. This may occur even in 4·8 per cent. of cases in an early stage of the disease. These are cases with limited lesions, and, at this period, might well be called 'favourable.' In severe cases the proportion mounts up to 18·3 per cent., while in the advanced type of disease, which forms Group III. of the Turban-Gerhardt classification, the proportion of laryngeal disease is almost double—namely, 31·5 per cent.

An inspection of the diagram (Fig. 1) shows that both women and men are increasingly liable to a laryngeal lesion with the progress of the pulmonary disease. Only one out of every twenty *poitrinaires* with an early lesion is liable to throat trouble; in more serious cases (that is, those in Group II. of the Turban-Gerhardt classification) the proportion may be one in five, and in the advanced cases of Group III. one patient in every three will have the disease in the larynx. This development—as will be shown later—diminishes so markedly the prospect of recovery that it emphasizes the great importance of diagnosing pulmonary tubercle in its early stage and persuading the patient to submit to the best treatment.

Region of Larynx Attacked

Tubercle may deposit in any part of the larynx, but it may help towards an early diagnosis if a keen look-out is kept on the region most commonly attacked. It is quite certain that the favourite site is the neighbourhood of the posterior commissure—that is, the inter-arytenoid area, the anterior surface of the arytenoid bodies, and the vocal processes (Fig. 2). The vocal cords come next in frequency, while the epiglottis and the region of the anterior commissure are attacked more rarely, and are generally late extensions of the disease. Now, I impress the importance of bearing this fact in mind, that it is just around the margin of the posterior commissure that the disease

* On the State of the Public Health. Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1923. His Majesty's Stationery Office, London. 1924. Price 6s.

is most curable, and yet it is an area which is frequently overlooked Reports are very commonly sent up with the remark that "the arytenoids are swollen," or that "the

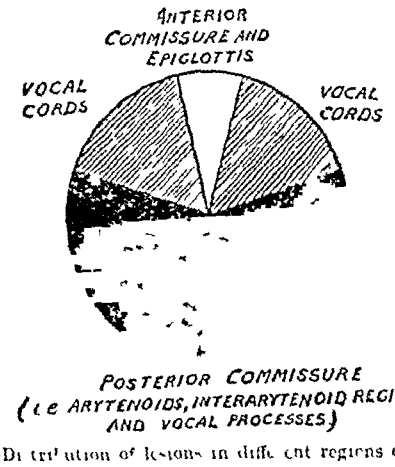

Fig 2.—Distribution of lesions in different regions of the larynx

cords are not ulcerated" But the latter is not the most common lesion, and by the time that an arytenoid is swollen the disease is advanced and generally hopeless

Prognosis of Tuberculosis in the Larynx

To forecast the possible course of a lesion in the larynx requires the careful balancing of a huge number of factors, general and local, and hardly comes within the scope of this lecture What the prospect is of a local cure may be estimated by a study of the accompanying table (p 843) which shows the results of treatment in nearly 500 cases of the disease Of much more importance to the general physician is an appreciation of what tuberculosis in the larynx counts for in regard to the mortality of pulmonary cases

The Prognostic Value of Tuberculosis of the Larynx in regard to Mortality

In treatises on medicine or on pulmonary tuberculosis it is not unusual to read that, if the disease attacks the larynx it "adds distressing features to the case," or increases the gravity of the outlook" These statements I entirely endorse, but I hardly think it is generally realized that this complication is such a serious one—only less in gravity than a secondary invasion of the meninges—and I hope that the following observations may help to strengthen the position of the physician by encouraging him to work for an early diagnosis and to insist on prompt and suitable treatment

Of the 2541 patients with pulmonary tuberculosis who were discharged from the King Edward VII Sanatorium Midhurst between 1911 and 1921 the proportion of those alive between one and ten years later was amongst those with a sound larynx, double that of those with tuberculous laryngitis Of patients found to have tubercle in the larynx during these ten years two out of every three were dead Of those with a sound larynx it is the reverse—two out of three were still alive Of all the 477 cases of laryngeal tuberculosis which passed through my service at Midhurst between 1911 and 1921 no less than 70·5 per cent are now dead

This darkening of the prognosis occurs in all stages of the disease (see Fig 3) Of patients with lesions in the lungs so limited that they were subdued in Group I (of the Turban-Gerhardt classification) 82·6 were alive at a date when 50 per cent of the patients with similar lung lesion but with the addition of a deposit in the larynx were dead In Group II the mortality of laryngeal cases is more marked—two out of three cases are dead while of those with a free larynx two out of three were still alive In Group III—that is advanced cases—the difference is not so marked, for the mortality is so much higher with advanced pulmonary tuberculosis that the added danger of a laryngeal lesion is not so noticeable Even in this group 42·3 per cent of the patients were still alive amongst those with a free larynx when only 22·7 per cent survived at the same date of those in whom it was affected

A glance at Fig 3 will show that the mortality of laryngeal cases in Group I is higher than it is among pulmonary cases with more extensive lesions of Group II but with a normal larynx (that is, a mortality of 50 per cent compared with 39·08 per cent) In Group II this mortality is 66·3 per cent, compared with a rate of 57·4 per cent in the larynx-free patients of Group III

Put in another way, a Group I patient (that is, a "slight" case) with a laryngeal lesion has a worse prospect than a Group II case with a sound larynx And a Group II case (that is, a "severe" case) with throat trouble has a gloomier expectation than if he had had a healthy larynx but lungs so involved as to be classed in Group III (that is, an "advanced" case)

Differently expressed, the discovery of a laryngeal lesion at once moves a case down to a lower group In fact, in our tabulation *of cases in King Edward Sanatorium* there are no laryngeal cases in Group I We think so badly of this complication that, even if only associated with quite early lung trouble, disease in the larynx moves such a patient down to Group II Therefore laryngeal tuberculosis cannot be listed in any group which might be termed "slight" or "favourable" Its discovery at once labels a case is "severe," and authorizes a physician to warn his client that treatment will necessarily, even in the most hopeful cases, be long and arduous In only too many instances (in 70·5 per cent of my fairly favourable selection) it will be his duty to advise the friends that the prospect of a recovery is so slight that it may be unjustifiable to submit the sufferer to any trying, dangerous, or expensive treatment

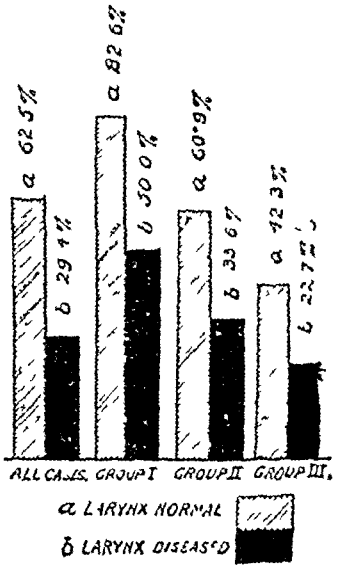

Fig 3.—Percentages surviving in (a) of patients (a) with larynx normal (b) with larynx diseased from 1911 to 1921

Results of Treatment

From these rather gloomy conclusions let us turn to my record of 119 cures To appraise them at their value I may be permitted to say that such a large total of well authenticated cases of healing in a larynx with tuberculosis has never before been published in this country The satisfaction of quoting this record is enhanced when I recall that in 1880 Morell Mackenzie wrote "The prognosis of laryngeal phthisis is always extremely unfavourable and it is not certain that any cases ever recover", and that as late as 1908 a well known German authority stated that

The cure of tuberculosis of the larynx is still to-day an exception" Sixteen years after these words were published I am able to refer to 119 "exceptions", many of them have been shown before sections of the Royal Society of Medicine, and some idea of the extent of lesion in which repair can be effected may be obtained by studying the illustrations shown on the screen A complete repair of the larynx has been obtained in no less than 25 per cent of patients with tuberculous laryngitis

Cures How Obtained

I have no doubt that the principal factor in obtaining these arrests has been sanatorium regime and the practical prescription of one or more of the three chief methods of local treatment namely, rest, silence, and the gain of cure is It certainly would be difficult to carry out the first two methods thoroughly except in a sanatorium In fact employment has always preceded the adoption of either application

But patients are cured—so far as local disease is concerned—*by the simple reduction of one's conditions*

whispers This figure gave 14 8 per cent as the proportion of cures in the 336 cases in which it was ordered It may seem a small proportion, but it is low because all laryngeal patients are advised to limit voice use to whispers, many of them had no expectation of complete cure and were only put on "whispers" to avoid aggravation of the local trouble, others amongst them had, in addition, cautery treatment, and are therefore listed under that rubric

Complete silence resulted in a cure in 23 instances, or in 34 3 per cent of the cases in which it was ordered The total of 23 cures out of 477 cases may seem small, but it was only carried out in 67 instances, for it was felt that such an ordeal should only be advised in promising cases The number is also reduced by the subtraction of some who, in addition, had cautery treatment The silence treatment was more successful with the women patients (41 6 per cent) than with the men (25 8 per cent) Women give a slightly higher percentage of cures, both with whispers and silence Their greater patience and endurance—or recovery power?—being most noteworthy in the ordeal of the silence cure

The *galvano-cautery* yielded 46 cures This method gives the highest proportion of satisfactory results in the 74 cases in which I tried it (=46 per cent), doubtless because the cases were carefully selected after being first watched, as a rule, for some months while under "whispers" or even silence In one case the patient was fourteen months in the sanatorium before his larynx and general condition justified galvano cautery treatment[3] This patient was able to earn his livelihood and remained well and active for years He then died of pulmonary haemorrhage the larynx never relapsed Another patient was a year under observation before the cautery could be used She required fourteen treatments It is seven years since the last, she is now free of bacilli and she earns her livelihood as a postmistress These cases show that this method may be long and costly, fulfilling part of the saying that 'the cure of tuberculosis requires a good stomach and a large purse!"

Results of Treatment by all Three Methods of Silence Whispers and Galvano cautery in 477 Cases

	Males	Females	Totals	Per Cent
Arrested	70	49	119	24 94
Improved	83	53	141	29.39
Status quo	111	76	187	39 20
Worse	15	15	30	6 29
Total	284	193	477	

Durability of Cure

After Silence—Of 8 men cured by silence, 3 are alive at periods of one, two, and four years after discharge The other 5 remained healed of their laryngeal lesions but have died from their pulmonary tubercle Of 15 women, no less than 10 are alive and well after the lapse of two to ten years

After Whispers—Healing has been maintained in some cases for three, four, and even ten years Fifteen out of 27 men, and 13 out of 23 women, are still alive and well

After Galvano cautery—Of 46 cures, 28 are still alive, and in 6 of them the cured condition has persisted for ten years As with the two preceding groups, the patients who are dead have succumbed to their pulmonary disease and, generally, without any laryngeal recurrence Even of these I have been able to calculate that the average duration of life, after healing was complete, varied from two years and eight months in the men and to five years and two months in the women

Benefit of a Healed Larynx—During these years the patients were able to use their voices, and this voice use was not only a pleasure to them, but it removed the anxiety and depression which so many patients suffer from when tubercle attacks the larynx The recovered voice also assisted them in their social duties and in gaining a livelihood

Lasting Laryngeal Cures—Thus of the 119 cases in which complete healing took place in the larynx 69 are alive at periods varying from two to ten years afterward Fifty are dead, and they have died, as a rule, with a still cicatrized larynx Their death usually, were due to the extent or virulence of their pulmonary disease

Proportionate Progress of Pulmonary and Laryngeal Lesions

The above references to the durability of healing in the larynx, while the disease in the lungs progresses, are sufficient to show that tubercle does not necessarily progress *pari passu* in both situations This latter view is still maintained, and, as it is not correct, it may occasionally mislead the physician

Improvement very commonly does proceed along parallel lines, and in the same way a retrogression in one is often followed by progress of the disease in the other For instance, a "flare up" of temperature is generally followed by development of active signs in the chest and an increase of the disease in the larynx But this is not constant I have known of tubercle developing in the larynx just as the disease had become arrested in the lungs (and remaining so for twenty years) and the bacilli had disappeared from the sputum On the other hand, I have frequently noted that the laryngeal disease had so far improved that the use of the cautery was indicated to complete the cicatrization, when I have received the report that the pulmonary disease was progressing Indeed, as recorded in the preceding paragraphs, spontaneous cure has taken place in the larynx in many cases, and has been maintained till the patient died of his pulmonary disease years afterwards But the reverse has never occurred—that is I have never seen a larynx getting worse while the pulmonary disease has improved It has occasionally in such instances, been reported to me that the lung trouble was *status quo*, but if the larynx did not mend the pulmonary disease inevitably, within a definite period, took on activity

This is useful knowledge for the physician a larynx may improve or get well, while the lung disease remains quiescent or gets worse, but if the disease in the larynx advances the pulmonary disease cannot possibly become arrested, and soon makes progress This again shows the value to the physician from the point of prognosis of periodic examination of the larynx

The Pessimistic Past of Tuberculous Laryngitis with its more Optimistic Outlook

The realization that of all my 477 cases, treated in a sanatorium during ten years 70 5 per cent are now dead is an arresting and a saddening thought Nearly all of them were young people, few of them had induced their disease by vicious living, many of them had incurred it largely by excess of unselfishness or by a too ardent devotion to duty, and in no inconsiderable number it was directly due to their patriotic services in defending their country in the great war This heavy toll demonstrates that tuberculosis in the larynx is always a serious complication of pulmonary disease Physicians would be well advised to assure themselves of its presence or absence in any case of tuberculosis It present it adds considerably to the seriousness of the prognosis and to the prolongation of the care and time required for successful treatment, even in cases otherwise early and promising

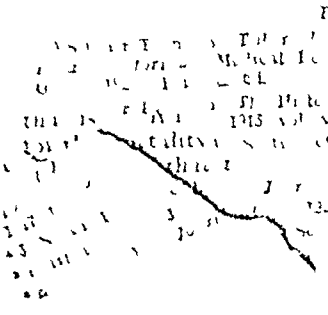
When the laryngeal lesion is extensive and active the outlook is particularly serious If the lesion is limited and becomes inactive it may be arrested, although the prospect of life may not be great From prolonged observations on nearly 500 sanatorium patients a cure of the laryngeal lesion may be secured in one out of every four patients These were, comparatively speaking, early cases But a much higher proportion of cures could certainly be obtained

if more cases of pulmonary tuberculosis were diagnosed while they are still Group I patients (that is, with only 4·8 per cent showing laryngeal lesions) instead of Group III (that is, with 31·5 per cent with the larynx involved) More cures could be effected if every case of persistent hoarseness or throat discomfort were earlier submitted to a skilled examination

Principles of Success in Treatment

It is manifest that a patient has a more sure hope of a quicker cure inside a well conducted sanatorium than he can expect otherwise Even if he remains in a sanatorium only long enough to learn how to manage himself, this sojourn is highly beneficial This is shown by the number of my cases which left Midhurst with the larynx still diseased but who kept up sanatorium principles and later on obtained complete and lasting cicatrization of their throat trouble

The chief local requirement is voice rest, which can be so easily carried out in a sanatorium but is elsewhere so difficult Out of 119 cases which were cured, the healing was obtained without other local treatment than voice rest (whispers or silence) in no fewer than 73 instances That such a simple treatment—though long and arduous for the patient—can be so effective should encourage perseverance with it when indicated



Local surgical methods of cure have all been abandoned by me as useless and frequently harmful My statistics show that a laryngeal lesion generally indicates an extensive lung lesion, or a very virulent infection, or lowered resistance As things are at present, the majority of patients with laryngeal tuberculosis soon die (70·5 per cent), they generally die of their lung disease Topical surgical measures in the larynx are only apt to hasten this, then successful local results have never been frequent or enduring, and we have, in the galvano-cautery, a safer and more certain help The galvano-cautery has, in my practice, superseded all other topical measures—cutting, injections, insufflations, application of lactic acid or other caustics I have never seen a single case in which it has done harm, although in some it has been abandoned as useless It effected a cure in 46 out of 74 cases in which it was tried (=62·1 per cent) Of these 46 cures, 29 are alive and well, 12 of them have now maintained their cure for ten years The galvano-cautery is the best local treatment we have at present In suitable cases it has replaced all other methods

Conclusions

The majority of cases of tuberculosis of the larynx do not recover It is necessary for the physician to recognize this, to try and determine which cases come within this category, and to act accordingly But these 119 cures are witnesses of the more hopeful outlook we now have for a fair proportion of patients of whom an authority has said that, forty-five years ago, "all were doomed to die the appearance of the disease in the larynx was the warrant of death"

The pessimistic past has now a more optimistic outlook As the Minister of Health said lately on a public occasion

The fight against tuberculosis was a long one, but it was a winning one At the recent Congress on Tuberculosis in Lausanne (August, 1924) it was shown by Sir Robert Philip that this fight is being won, not simply by the population becoming immunized or by such general advances as improved national health and hygiene, but by the measures of direct attack organized and inspired by our profession

CERVICAL RIBS IN CHILDREN.

BY

A. H. SOUTHAM, M.D., M.Ch.Oxon., F.R.C.S.Eng.,

ASSISTANT SURGEON ROYAL MANCHESTER CHILDREN'S HOSPITAL, ASSISTANT SURGICAL OFFICER MANCHESTER ROYAL INFIRMARY, VISITING SURGEON STEYNING HILL HOSPITAL, STOCKPORT,

AND

W. J. S. BYTHELL, O.B.E., B.A.Cantab., M.D.Vict.,

HON. RADIOLOGIST TO THE ROYAL MANCHESTER CHILDREN'S HOSPITAL AND THE SALFORD ROYAL HOSPITAL, CONSULTING RADIOLOGIST TO THE MINISTRY OF PENSIONS

Ever since Sir William Thorburn[1] in 1905 showed that certain symptoms in the upper limb were associated with the presence of cervical ribs, an increasing number of reports upon this condition have appeared in medical literature Supernumerary ribs have been recorded in both sexes and at all ages Thorburn states that the earliest age he has met with them was the seventeenth year Sir William Turner[2] refers to a case described by Rosenmuller in an embryo of six months, and Stiles[3] has also recorded a case in a female infant of 18 months Nevertheless, comparatively little attention has been directed to the presence of cervical ribs as a possible cause of symptoms in children, and this paucity of data is all the more striking when one considers the increasing use of radiography at the present time It is undoubtedly true that in the majority of cases the symptoms produced by cervical ribs do not appear until adult life is reached, and that in young children attention is perhaps only drawn to their presence by a prominence in the neck or by the accidental discovery of the condition in a radiograph of the neck

The four cases of cervical ribs in children described in this paper have recently come under our observation and have led us to make further investigation into the frequency of their occurrence The result has been to convince us that this condition has not received the consideration which it deserves

The first of the four cases occurred in a girl 4 years of age, and although the ribs were causing no pressure symptoms, the child was brought to the Royal Manchester Children's Hospital early this year on account of two hard masses above the clavicle The swellings were very prominent and extended from the spine to the first dorsal rib Radiological examination showed that bilateral cervical ribs were present In the absence of any symptoms no treatment has been deemed necessary up to the present time

In the second case, however, the pressure effects were so definite that operative treatment was clearly indicated The case is worthy of detailed record, as it is unusual to find such typical symptoms at so early an age

M. G., a girl aged 12 years, was brought to the Manchester Northern Hospital in June, 1923, complaining of neuralgic pain in the left forearm and hand, and a constant irritating cough She was first seen by Dr. Mather, who was unable to find any clinical signs in the chest to account for the cough, but discovered a swelling in the left side of the neck He referred the child to one of us for further investigation and treatment as being a case of suspected cervical rib Examination revealed a hard bony tumour above the left clavicle with some atrophy of the [illegible] muscles of the left hand Pain was complained of along the ulnar border of the forearm and hand, but no vasomotor or trophic disturbances were present A radiogram demonstrated the presence of a large cervical rib on the left side arising from the [illegible] cervical vertebra Operation for its removal was advised, and was carried out shortly afterwards A flap was raised [illegible] upon a border of the clavicle and behind the sterno-mastoid muscle, the brachial plexus being thus exposed The [illegible] connecting the cervical rib to the anterior trunk [illegible] to the first rib was clearly demonstrated and dissected free [illegible] rib at its dorsal end firmly [illegible] Division [illegible] anterior portion [illegible] The [illegible] was damaged, but [illegible]

Bleeding points were secured and the wound closed firm pressure being applied with a pad and bandage Recovery has been satisfactory the wasting has now practically disappeared with massage and there is no longer any pain

The portion of the rib removed measured 1¾ inches in length. The anterior extremity ended in a joint with an articular cartilage and synovial membrane which joined it to the first rib The attachments for the scalene muscles were clearly seen after its removal

In the third case, also a girl aged 12 years, there was a pair of cervical ribs causing distinct swellings on either side of the neck there were no pressure symptoms in this patient requiring treatment

The fourth case was also found in a girl, here symptoms made their appearance at the age of 15 A right cervical rib was subsequently removed on account of the pain in the arm and the wasting of the small muscles in the hand, with fairly satisfactory results

This succession of cases in the course of a few months suggested to us that it would be of interest to examine the records of the x ray department of the Royal Manchester Children's Hospital On doing so we discovered that in the last two thousand x ray examinations, including all parts of the body, in no less than nine cases were cervical ribs reported to be present The details of these cases are as follows

No	Sex	Age		Clinical Diagnosis or Symptoms
1	F	12 years	3 months	Cervical rib
2	F	4		Cervical caries
3	F	10	11	Torticollis
4	M	9	7	Cervical caries
5	M	2	1	? Cervical caries—? trauma
6	F	12	10	Cervical rib; paresis of left arm
7	M	5		Torticollis—? cervical caries
8	F	4		Cervical rib
9	F	7	7	Torticollis—? cervical caries

It is interesting to note that the disturbances due to the presence of cervical ribs gave rise to the clinical diagnosis of cervical caries in five cases, whilst in three instances their presence was associated with spasmodic torticollis In many instances the differential diagnosis can only be made by means of radiography, and in most of these cases the presence of cervical ribs could not be definitely established on palpation, even after their demonstration by x rays

The incidence of such a large number of cases in the course of fifteen months has convinced us that the occurrence of cervical ribs is more frequent in childhood than is generally supposed to be the case, and that we are well advised in drawing attention to the condition

Most radiologists will we think, agree that cervical ribs are less frequently detected in children than adults Although the records of the Royal Manchester Children's Hospital show a comparatively large number of cases in a short period, we are inclined to think this is a somewhat unusual occurrence

With regard to the relative frequency with which cervical ribs are found, there are no definite data available Fischel of Prague[1] reports that in routine necropsy examinations over a period of four years the condition was found in 1 per cent of all bodies examined From the x ray appearances observed in our group it appears that in the majority of cases cervical ribs are only partially ossified at birth and are not revealed by x rays until later in life In one of our cases where well marked cervical ribs were palpable a radiograph showed that only a small portion of the rib was ossified The dorsal ribs are ossified at birth, but at puberty secondary centres appear, and ossification and growth are not completed until about the twenty-fifth year It is probable, therefore, that the ossification of a more or less rudimentary rib may be still further delayed, and this is suggested in our series of radiographs We have seldom met with really large cervical ribs in children demonstrable by x rays, and this supports the view that their growth and ossification are not complete till later life when the incidence of cervical rib appears to be more frequently recognized With the growth of the child the dorsal ribs increase in size and length, and cervical ribs will no doubt do likewise

The fact that the onset of symptoms in these cases is usually delayed until after adolescence is accounted for by Todd[2] as being due to the descent of the shoulder-girdle, which is not complete till the third decade of life An additional factor in causing dropping of the shoulder-girdle has been suggested by Stopford[3]—namely weakness of the supporting muscles, producing stretching of the nerve trunks over the rib We suggest, as a further explanation why symptoms are delayed till adult life is reached the fact that ossification is not complete till after adolescence It is natural to suppose that the increase in growth and size of the rib may lead to greater pressure on the nerve trunks resulting in the nervous disturbances encountered in these cases It is interesting to note in this respect that in our cases the pressure effects were most marked in those children possessing more completely ossified and therefore larger ribs On the other hand it is undoubtedly true that in adults severe symptoms are sometimes caused by comparatively small ribs and that even a large pair of cervical ribs may produce no ill effects of any kind

Cervical ribs are for some unknown reason found to be more frequent in women than men and this is also borne out in our series, where ten out of thirteen cases occurred in the female sex They are said to be bilateral in about 60 per cent of cases, and in the group under review were bilateral in all except one case

In many cases of cervical ribs no treatment will be found necessary Where, however symptoms are present a short course of non-operative treatment to promote development of the muscles supporting the shoulder girdle should be tried Should however no improvement result after two or three weeks, surgical treatment consisting in removal of the rib is indicated When there is marked atrophy of the muscles of the hand their recovery is rarely complete and this should be an additional reason for avoiding unnecessary delay Where operation is undertaken before there is serious damage to the nerves it usually results in rapid subsidence of the disturbances

Our thanks are due to Professor Stopford for valuable assistance and advice in the preparation of this paper

Conclusions

1 Cervical ribs are congenital abnormalities and may be found in children at all ages

2 In thirteen recorded cases twelve were bilateral and ten occurred in girls

3 Their diagnosis will frequently only be made after radiographic examination

4 In the majority of cases symptoms do not appear till adult life is reached

5 The delay in the onset of symptoms may be due to delayed ossification of the rib, which is not complete till about the twenty-fifth year

6 In young children, however, there occasionally give rise to very definite symptoms in the upper limb similar to those seen in adults

7 In others their presence may lead to a diagnosis of spinal caries or torticollis and the differential diagnosis can be established only by radiography

8 Only rarely will treatment by operation be found necessary

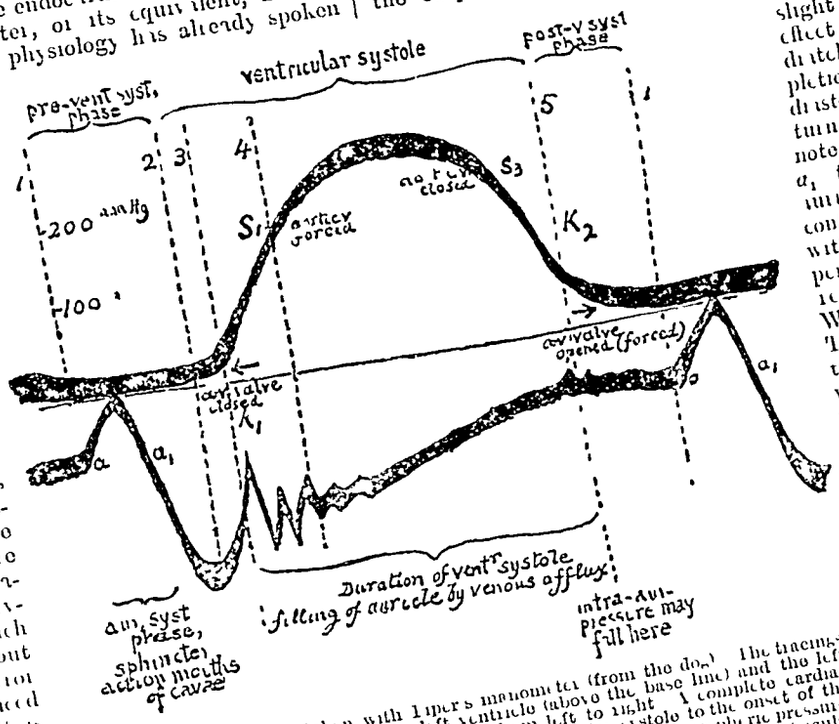
VENOUS PULSATIONS AND VENOUS TRACINGS.

(A Supplementary Note)

BY



HARRINGTON SAINSBURY, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO THE ROYAL FREE HOSPITAL AND THE VICTORIA PARK HOSPITAL FOR DISEASES OF THE HEART AND LUNGS

In the BRITISH MEDICAL JOURNAL of April 14th, 1923 (p. 626), certain criticisms on the current interpretation of the polygraphic tracings, obtained from the root of the neck, were brought forward, and, in view of the discrepancies which seemed to show between the interpretation and the actual sequence of events in the cardiac cycle, I ventured to suggest that the whole subject should be referred to the physiologists. Upon further consideration of the matter, and after careful study of the endocardiac pressure tracings taken with Piper's manometer, or its equivalent, I have come to think that perhaps physiology has already spoken to some purpose, and it is this pronouncement which I desire now to bring forward in an endeavour to complete and confirm the argument previously presented.

In Piper's manometer the elimination of the instrumental error, by the utilization of the beam of light in lieu of the mechanical lever seems to have brought the recording apparatus almost as near perfection is possible. There still remains the inertia of the vibrating membrane carrying the mirror which reflects the beam, but this source of error has also been reduced to a minimum. It is this instrument which has disproved the presence of negative pressures in the chambers of the heart during the act of diastole.

The figure is reproduced from Starling's *Human Physiology* (third edition, 1920) by kind permission of the author and the publishers (Messrs. J. and A. Churchill). Some letterings and numberings have been added to the figure, also some descriptive words, but no alteration of any kind has been made in the tracing itself.

Intracardiac tracings taken with Piper's manometer (from the dog). The tracings are taken simultaneously from the left ventricle (above the base line) and the left auricle (below). The curves are to be read from left to right. 1 complete cardiac cycle is shown, namely from the onset of one auricular systole to the onset of the next. The base line (with opened thorax) represents the zero of atmospheric pressure. Ordinate 1 marks the onset of the auricular systole. Ord. 2 the onset of ventricular systole. Ord. 3 the point of closure of the auricular valve. Ord. 4 at S_1 the forcing of the aortic valve. Ord. 5 K the opening (forcing) of the auriculo-ventricular valve. The point of closure of the aortic valve has been placed arbitrarily at the point S, to indicate that it will stand higher on the curve than S_1 because the intra-aortic pressure will be at its highest towards the end of ventricular systole at which time the aorta will be most distended. On the auricular curve, a marks the onset at the ending of the auricular systole.

Let us now endeavour, along these curves, to follow the sequence of events within the auricle during the cardiac cycle. We start with the auricular systole.

At whatever level of pressure the intra-auricular pressure may have stood at the moment immediately preceding auricular systole, this event now superimposes its own reinforcement. The pressure line starts at *a*, rises more or less abruptly, culminates, and then falls, until it reaches the point a_1, the fall of the line reproducing approximately the line of ascent. At the point a_1 the auricular systole is wholly spent, at the same moment the ventricular diastole is completed. At this point Hurthle has detected a slight intraventricular rise of pressure which will stand for the auricular systolic effort now transformed into tension of the ventricle.* Upon withdrawal of the auricular systolic effort thus intraventricular pressure, however slight its rise, will be positive as compared with the intra-auricular diastolic pressure then ruling, and it must take effect backwards (since there is no outlet forwards). But in opposition to the ventricular recoil stands the auriculo-ventricular valve, the cusps of which, therefore, will first be floated into position and then carried back under slight tension. This effect will follow immediately upon the completion of the auricular diastole. It now we turn to the tracing we note that at the point a_1 the falling intra-auricular pressure line continues its descent without any break or perturbation until it reaches its minimum. What is the conclusion? That this primary ventricular recoil is too weak in effect to register itself within the auricle or let alone to record itself in the internal jugular vein."†

Auricular diastole is thus silent, but what of its antecedent auricular systole? The tracing precents very definite wave like rise and fall. Is this an undulation? No, it is just a pressure or tension curve, no more, corresponding in this respect exactly to the curve of the ventricular systole above the base line, but it may beget an undulation if there be any point of outlet from the auricular chamber. There are two outlets—one forwards into the ventricle, one backwards into the veins feeding the auricle. Without doubt there will be a fully developed *forward* effect as the blood is propelled into the ventricle, but this can have nothing to say to us who are watching events at the root of the neck,‡ for the internal jugular vein can only register backward developments arising within the auricle. Now, as to these latter, let us consider first the purpose of the auricular systole and ask, What is the auricular walls reinforced with muscular fibre? The answer is, In order that the auricles may become contractile chambers, and so may reinforce the spent blood of the circulation, fallen to a minimum in the great thus they will ensure a better filling of the ventricle,

---

* It must be borne in mind that the tracings above and below the line shown bear no relation to each other in regard of their *force values*. For whilst the intraventricular values are measured in millimetres of mercury and in hundreds the auricular values are measured in millimetres of water and in tens, so that an actuality the auricular curve is but one-tenth the height into which it is brought into relation with the ventricular curve. Another point should be kept in mind, if brought into the figure as it stands for with the base line on practically its upper and lower limit

will facilitate the general onward movement of the venous blood. Let us next look at the disposition of the fibres, and in particular take note of their arrangement at the mouths of the tributary veins. It will be seen that they encircle these inlets and in the act of contraction must sphincter-like, close them more or less. Here comes the crux of the matter: how complete is their action? As to this, I understand from Professor Starling that precise physiological determination is lacking, but in its absence it is probable that certain conclusions may be drawn and will find general acceptance, these are:

That in health we may expect the sphincter action at the mouths of the two cavae and of the pulmonary veins to be a very appreciable quantity during auricular systole: seeing that both structure and purpose point in this direction, for how is the auricle to get up a sufficient head of pressure to complete the ventricular filling if there is an abundant reflux leakage into the great veins at each systole? At any rate it must be clear that by *as much as there is backward reflux at each systole the auricle will fail in its propulsive effort*. And again, the object of the auricular systole being to facilitate the general onward movement of the venous blood, how would that purpose be served by an abundant reflux, which must oppose that movement? The argument gains in authority when we regard the great capacity of the tributary veins, especially of the cavae, their thin, therefore distensible, walls, and further when we remember that in health the veins are underfilled, all the circumstances thus conspiring to favour reflux in the absence of a pronounced sphincter action.

The force of these deductions will not be weakened because in disease, marked by engorgement of the right heart and of its tributary veins, we are obliged to admit that sphincter action is almost certainly in default, more or less, and that in paralysis of the auricle (fibrillation) it must be in complete abeyance, rather will the argument be strengthened because we then see before us the circulatory failure which attends upon or is accentuated by a failure of sphincter action. Pending the physiological determination of this matter we may sum up as follows:

(*a*) Supposing that in health sphincter action at the mouths of the cavae is complete, there will be no possibility of an *a* wave in the internal jugular vein as a backward propagation effect due to auricular systole.

(*b*) Supposing, on the other hand, an *incompleteness* of sphincter action, whether in health or disease, this, *pro tanto* will favour the propagation of an auricular systolic wave into the superior cava, which may or may not reach the internal jugular vein in measurable strength.

(*c*) But that, in respect of the last-named conclusion we must *not forget* that even in health the force value of the auricular contraction is very small, whilst in disease with right-sided congestion of the heart, it will be more or less impaired even to complete extinction.†

(*d*) Finally, it must be repeated, Piper's tracing of the auricular systole tells us only of a rise and fall of pressure *within the auricle* of events within the tributary veins, associated or not, it says nothing, directly: that is a matter of inference and as such is debatable.

Are there any possibilities of an *a* wave caused by the auricular systole yet not due to propagation backwards from the cavity of the auricle? Physicists have contended that there are, they point to the effect of suddenly interrupting the flow of a stream of liquid as by the turning of a tap. The rebound which then takes place at the site of the interruption is a familiar manifestation. Dr Samways‡ in particular has argued for this mode of origin of an *a* wave propagated back from the *closed* mouths of the tributary veins, and Professor Starling also admit the possibility of this mode of action. Whether a phenomenon which holds for a stream of water flowing under considerable pressure (as compared with the venous pressures of health and disease) through a system of rigid tubes would find its counterpart in the low pressured afflux of the great cardiac vein, the walls of which are thin and elastic and in general incompletely filled, this I must leave to the physiologists and physicists to decide, but if it should be established it would surely demand *complete occlusion* of the mouths of the auricular veins during the early auricular systole.

The next intra-auricular event comes with the forcible recoil of the auriculo-ventricular valve, which is effected by the onset of ventricular systole. We have already referred to a slight recoil of this valve bringing the cusps into position which will take place at the end of auricular systole when the force which completes the filling of the ventricle is withdrawn. The cusps thus in position will present the valve as a cone with its apex towards the ventricle, but now with the rapid and forcible contraction of the ventricle the valve will be driven back towards the auricle along with the contents of the cone, and an impulse imparted to such residual blood as may have been left over in the auricle at the end of auricular systole augmented further by influx from the cavae, which upon cessation of auricular systole will *at once unload their excess of blood* accumulated during its persistence. This stronger movement of the valve begins quite early in ventricular systole, as shown at K_1. What is its effect within the auricle?

We see in immediate sequence certain sharp-peaked oscillations of the pressure line, at times still more pronounced than here shown, according to Professor Starling. These oscillations have the characters of true undulation of the ridge and trough type and we note their gradual subsidence whilst keeping to type. Evidently the contents of the relaxed auricle have been set in motion by the impulse they have received. The dying away of the perturbation is a familiar inertia effect which may apply to the contents of the auricle only or be due to the swinging of the valve, the result of a jerking action of its attached muscles, which would communicate itself to the contents. Be this as it may, here is the *onset* of ventricular systole announcing itself unmistakably. But the contents of the auricle are in free fluid communication with the blood in the tributary veins, since in the relaxed auricle there is *no* obstructing sphincter action, therefore to the development of an early or earliest ventricular systolic wave in the internal jugular vein there is no impediment. It is for this that I have contended—namely, that admitting, for argument's sake, the presence of a pre-ventricular systolic *a* wave, the next event in the cardiac cycle must be styled a *c* wave, since it marks the onset of ventricular systole.

From this point onwards, proceeding with the cardiac happenings, the contents of the auricle are shut off from all communication with the ventricle (assuming that the auriculo-ventricular valve holds), so that nothing occurring within the ventricle can propagate itself backwards into the auricle until the auriculo-ventricular valve opens again, and till this happens the auricular contents are solely under the influence of the venous afflux via the cavae.

It will be convenient here to leave the intra-auricular developments for a while in order to discuss a wave marked *c* on the polygraphic tracing. This wave is placed directly after the *a* wave, and, so situated, it does not merely take precedence of the wave caused by the onset of ventricular systole which we have just been considering, and which figures so prominently on Piper's tracings, but completely ousts it inasmuch as the latter appears nowhere on the polygraphic record. The *c* wave is held to originate in the impulse which the carotid beat transmits to the adjacent internal jugular vein, and that all adjacent structures must feel this impulse is indisputable. The contents of the vein therefore will be set in motion, but the question is, At what point of time does this incidence take place? The arterial pulse originates on the left side of the heart at the aortic valve at the moment when

* See Henle's *Handb. d. Gefass lehre d. Menschen* (second edition 1876), Fig. 35 and 36, pp. 48 and 49). These figures have the more authority in that I do not discover them to have any *ad hoc* applicat on by Henle.

† The question of hypertrophy of the right auricle is so rare an occurrence as to be negligible clinically, and left auricle activities of course do not record themselves in the internal jugular.

‡ BRITISH MEDICAL JOURNAL, April 13th 1912. I regret that I had never looked Dr. Samways's views as to the sphincter action of the mouths of the auricular veins when I wrote my paper (BRITISH MEDICAL JOURNAL, April 14th 1923).

the rising intraventricular pressure forces the valve This moment is marked S_1 on Piper's tracing If now we look at the figure we see that a very appreciable interval* lies between the closure of the auriculo-ventricular valve, which takes place almost immediately after ventricular systole has begun, sometimes "synchronously with it,"† and the opening of the aortic valve The actual length of the interval can be found by measuring the distance of the point S_1 from the ordinates 3 and 2 respectively, and if we do this with compasses we find that it varies from one-fifth to somewhat over one-fourth of the total duration of the ventricular systole, counting from the closure of the auriculo-ventricular valve until the opening again

From Piper's tracing, then, it is quite clear that in early ventricular systole undulation arises within the auricle, at or immediately after the closure of the auriculo-ventricular valve, and that it precedes the arising of the arterial pulse at the aortic valve by a well marked interval How are we to reconcile the conflict here seen between the heart happenings and the polygraphic record?‡ As it stands there are two cardiac events which are capable theoretically of wave production within the internal jugular vein—yet the polygraph shows us only one wave, and that wave is attributed to the second event, to the complete exclusion of event No 1 Why? Let us suppose that each cardiac event starts a wave, and that each wave makes for the same point in the internal jugular vein—what will happen? (1) There will be two waves, if these arrive at different points of time, (2) if they happen to arrive simultaneously, there will be one large wave, provided that the two waves are in like phase, for then they will reinforce each other, (3) there will be one diminished wave if they are in opposite phase, for then they will clash and cancel each other more or less, (4) there remains as a final possibility that, still being simultaneous, the two waves will cancel each other wholly, they being not only in opposite phase but of equal force value, according to the well known physical law of interference

Let us now return to the intra-auricular happenings which upon the subsidence of the perturbation caused by the abrupt closure of the auriculo-ventricular valve, were left under the sole influence of the venous afflux gathering behind the shut valve As I have previously stated, this afflux itself begets no pulsation Under these conditions what should we expect? What else but a gradually mounting pressure line as the blood accumulates in the auricle This rise of pressure would of necessity communicate itself backwards to the tributary veins the cave and their branchings including of course, the internal jugular, indeed the cave and their branchings, together with the auricle will form but one continuous cavity, since the auricle is in diastole and therefore no sphincter action is in operation The auricular congestion would therefore involve a venous congestion, and in the veins the pressure rise would follow the same course, mounting steadily by a summation of small quantities And what do we see in Piper's tracing? This seltsame gradual and smooth rise throughout the continuance of ventricular systole, which rise presents nothing of the nature of a wave, being just a tension curve At the end of the systole, upon the opening of the auriculo-ventricular valve, we do see, however, a slight perturbation and the ascending pressure line gives place to an almost horizontal plateau What has happened? The word opening is applied to the valve makes a wrong impression it suggests the active opening of a door This is not the case we may liken the valve action to that of a swing door open, freely in one direction but unable to move in the opposite direction beyond the point of closure The rising intraventricular pressure held the door closed during the whole of the systole, but upon its cessation—that is, upon the withdrawal of the muscular contraction—there was simultaneously a withdrawal of the holding force and the door was left, a passive structure, free to move under the force of the accumulated intra auricular congestion This force is, comparatively, very small, it is represented by the stretch of the auricle and the stretch of the thin-walled veins which feed it, but in the end these distensions do suffice to push open the valve (which opposes only its own inertia, a negligible quantity), and then they proceed to separate the relaxed ventricular walls, filling the ventricle as far as they are able In this act of ventricular filling the relaxed walls play a wholly passive part (for there is no negative pressure generated therefrom, no suction exerted), but the walls of the ventricle being much thicker than those of the auricle and, *a fortiori*, than those of the veins, these do oppose an appreciable inertia to the unloading of the auricle and its veins Accordingly we shall not be surprised to discover that, considering the smallness of the forces engaged, the unloading takes place quickly and with but slight falling off of the intra-auricular pressure line Consulting the figure, this corresponds precisely with what we have been led to expect from the physics of the problem I gather from Professor Starling that Piper's tracing is a typical one—that is, it represents an average result—and consequently the typical pressure curve within the veins communicating with the auricle will repeat exactly the form of the curve of the intra-auricular pressure as shown in the tracing The average case, therefore, will present no wave of venous "stasis" (accumulation) either in auricle or vein during the course of the ventricular systole subsequent to the disturbance on the closure of the auriculo-ventricular valve

But whilst we may regard this course of things as the rule, the exception may show us a more or less pronounced divergence In fact, Straub's intra-auricular tracing (taken from the cat)* does show us such a variant with a marked fall of pressure at the end of the ventricular systole How is this to be explained? Perhaps as follows Supposing the walls of the right ventricle to be less developed muscularly than usual, and therefore to approach more nearly to the auricular wall in thickness, supposing for some reason or other the tone of the muscular fibres be lowered—then upon cessation of ventricular systole the forces opposing ventricular dilatation will be greatly diminished and the congested auricle will be able to unload itself with comparative ease, causing therewith a more or less marked fall of pressure Straub's result would then be reproduced †

Be the explanation what it may, the fact of the variability remains, but the point to observe is that in those cases where the fall in pressure is "very distinct" at the end of ventricular systole, the rise and fall of the auricular pressure line may simulate a wave However, that we are then dealing with a simulacrum and not with a true undulation appears unmistakably in this, that the upstroke of the tracing is not repeated in the down stroke, the pseudo wave presenting a *gradual* ascent but a *sudden* descent ‡ Accordingly this asymmetrical tracing which the auricle yields, and which the contents of the internal jugular must reproduce exactly, will always contradict the curve of the polygraphic tracing, which in its sharp rise and fall, as figured, reproduces exactly the characters of the waves *a* and *c*, and therefore does not correspond in any sense to the theory of its production—namely, *by slow accumulation and sudden relief* In point of fact the intra auricular tracing which obtains after closure of the auriculo-ventricular valve and persists till it reopens is just a pressure curve and nothing else

Briefly, then, it comes to this, that when we compare the polygraphic record of the pulsations at the root of the neck, *as interpreted at present*, with the sequence of acts in which the cardiac cycle exhibits, according to the experimental findings of physiology, we discover a point of disagreement which forbids the utilization of that record for these purposes so long as the disagreement lasts

---

Sir James Mackenzie describes this interval as a minute portion of time (*Diseases of the Heart* third edition p 52)

A CLASSIFICATION OF CHOREA IN RELATION TO ITS CAUSES *

BY

CHARLES J MACALISTER, M D, F R C P

Over a period of many years a large number of cases of chorea have passed through my hands at the Royal Liverpool Hospital for Children at Heswall, and an opportunity has thus been afforded for investigating the causes of the disorder Although chorea is classed as a disease and is described as such in the textbooks, it really is a condition of a neuro-muscular inco-ordination which may result from very different causes It is a symptom rather than a disease, and I have come to classify it with reference to its origin, and not to mass all the cases under a single generic title Thus we have

1 The ordinary rheumatic or toxic type
2 "Stock-brained" cases related to an inherited tendency
3 A climacteric type

There is often little to distinguish these cases so far as the movements of inco-ordination are concerned but some of the associated phenomena present considerable distinctions

One of the first lines of inquiry consisted in a primary classification of all the cases into those which were rheumatic or developed endocarditis or pericarditis and those which did not and it appeared that the latter were often ascribed to fright or mental upset or some peripheral source of irritation, so that we had (1) rheumatic choreas, and (2) fright, etc , choreas

Next came a careful scrutiny of the histories of both types, and the interesting fact was revealed that in the second class the children were sometimes left-handed themselves or, being right-handed, came of a left handed stock, whereas the rheumatic children presented this kind of history in a very limited number of cases—probably representing rheumatism in children having the hereditary factor referred to It was on this account that the non-rheumatic cases became styled "stock brained choreas" and it is with these that I shall mainly deal here

In a few instances children suffering from this form of chorea have belonged to families in which there were stammerers—a fact which throws some light on the nature of the condition The choreic movements probably represent a gross motor ataxia or inco-ordination which may be regarded as analogous to vocal stammering An example of this was seen in a boy (Robert S), aged 6, who had well marked chorea, ascribed to the excitement of going to school for the first time He was left-handed The only other child, a boy, was right-handed and a stammerer The father was a left-handed stammerer and so was his brother Another similar case was seen in a girl who had chorea accompanied by acute vocal stammering which resulted from terror She was left-handed and had a stock brained history I mention these cases simply to indicate the suggestive relationship which probably exists between this type of chorea and stammering which has long been known to be in some way associated with familial left-handedness

I have a large collection of cases of chorea presenting this stock brained history, many of them acute, and so far as general symptoms are concerned in no way different from the rheumatic ones The history is in some cases direct in others collateral It will suffice if I quote some examples of each to illustrate my point

1 Margaret K aged 9 Severe and prolonged chorea Left handed Both parents right handed Four maternal uncles left-handed This child had rheumatism two years before the attack

2 John D aged 13 Mild chorea no history of rheumatism attack followed a small operation Left handed Has a right handed sister Father's family all right handed Mother mother's paternal grandmother father and sister left handed

3 Robert S aged 6 Severe chorea the result of fright no rheumatism no cardiac symptoms Left handed Father left handed and a stammerer one brother right handed and a stammerer Father's brother stammered Mother even letters and a second brother right handed and normal

4 Henrietta H aged 8 Severe chorea the result of being knocked down by motor Right hand d Father right hand d mother left handed No history of rheumatism no cardiac symptoms

5 Edward J aged 7 Severe chorea no rheumatism or cardiac symptom Left hand d tammered occasionally for three months before the attack Mother father left handed

6 Thomas F aged 11 Severe chorea the result of accident No rheumatism or cardiac symptom Right handed Father and mother right handed Mother has two left hand d brothers Second attack of chorea followed dog bite

7 Elsie C aged 6 Severe chorea the result of dog bite No rheumatism or cardiac symptoms Right handed Father and brother left handed

8 Eileen A aged 8 Severe chorea the result of fright (father threw paraffin on fire) Left handed. Father left handed mother right handed

9 Hilda O aged 8 Severe chorea—frightened by a dog Right handed Parents right handed Has left handed brother and aunt

10 Muriel D aged 6 Severe chorea—knocked down by bicycle No rheumatism or cardiac symptoms Right handed Mother mother and brother left handed

11 Ada D aged 12 (sister of above) Severe chorea—a cribbed to sister's illness

In all probability these choreas do not occur in children who come of a pure right-handed strain, nor would they in a purely left handed one if such existed Right-handedness and left sidedness are both hereditary, but the vastly larger proportion of right-handed people renders it impossible that there should be a pure left-handed strain in any family – that is one uninfluenced by a right handed dominance

From the histories which I have collected I gather that it is where there is a partial or reproduced transposition of cerebral function that we find the explanation of these cases—that is, they occur in children who are right-handed, but where there is a stock brained left-handed influence at work and in left-handed children where a reproduced right-handed inheritance produces its influences As a consequence of fright or other disturbance an unbalancing of co-ordination is brought about owing to some unusual relationship of function on the opposite sides of the brain

To revert to the stammerer we have this kind of involvement of the speech apparatus Stammering in a right handed person may result from a determination towards left-handedness with a dominant left cerebral speech centre whereas in the left handed person it may result from there being a determination towards right-handedness with a dominant right cerebral speech centre Hughlings Jackson, in his writings on the speech centre regarded the centre in the left brain as being the leading centre, its fellow in the right brain as an automatic one

It was on this basis that he accounted for the repetition of words and recurring utterances or sentences in a barrel organ" way in some cases of right aphasic hemiplegia He gave examples showing that these utterances often expressed the last call of the individual when struck down by the apoplexy I recollect a case of the kind where the patient from the time of his seizure until his death repeated the words "I want some brandy"—no doubt the result of his feeling sick and faint when the haemorrhage occurred Hughlings Jackson explained that these expressions probably come from the undamaged right automatic centre after being initiated in the left one immediately before it was put out of action Thus there is a double cerebral service It this be the case, it no doubt throws light on the relative functions of the two centres in a normal individual One can well imagine that where a stock brained influence impresses a tendency for automatism in a leading centre or for a centre having automatic functions to also on leading one the inco-ordinations expressed as chorea might easily be brought about the slender balance being upset under the influence of fright or other emotional or peripheral disturbance Whatever the explanation, the fact remains that here is this type of chorea which occurs in children presenting a stock brained history

Before parting from this type I may mention three examples of congenital aphasia which have come to my notice Two of them (girls) were left-handed, and all presented a collateral maternal history One of the two girls was mentally defective, the other, aged 6 was absolutely bright and quite up to the standard of intelligence

* Presented at the Association of Physicians of Great Britain and Ireland in 1923 and read at the Liverpool meeting of the Children's Section of the Royal Society of Medicine at Liverpool June 1924 with illustrative cases

for her age Although she could not speak, like the lesional aphasics, she could hum tunes and tried to sing with words The third case was a boy (G B) aged 2 years and 10 months, who has never spoken He makes efforts to speak like a child stammering very badly He is a well proportioned child for his age, but his mental condition is difficult to estimate His mother considers him quite intelligent He is right-handed, but comes of a left-handed stock —that is to say, his mother is right-handed but her brother and sister and her mother also are left-handed In these cases suggestion of lack of cerebral correlation again arises I had one case of a left-handed boy who only began to stammer when an attempt was made to make him a right-handed writer

A further outcome of this inquiry into the histories of the non-rheumatic choreas has indicated another causal factor which must not be overlooked The condition occurs in both sexes, but the majority of the cases recorded were girls at or about the period of puberty presenting, as so frequently happens, certain constitutional disturbances manifested by the complexion becoming blush or heliotrope, the hands and feet cold and blue, the heart large and palpitating, the liver somewhat small, and the thyroid enlarging Here we have an unestablished balance of the internal secretions and a tendency to nervous upset Chorea is not uncommonly related to this condition, and the cases constitute a class by themselves—the climacteric choreas As in the stock-brained cases, the disorder is often precipitated by emotional causes In the one it results from a chemical or metabolic inco-ordination, in the other from an anatomical one

I am indebted to Dr Simonne Thompson and to my resident physician, Miss Norah Walker MB, ChB for having taken much trouble in tracing the stock brained histories of every case of chorea, whether rheumatic or otherwise Since leaving the Royal Liverpool Children's Hospital at Heswall Miss Walker has carried out an independent investigation and has collected a considerable number of cases which confirm the above findings

ACUTE APPENDICITIS IN A CHILD COMMENCING WITH DIARRHOEA AND CONVULSIONS

BY

BERNARD MYERS, C.M.G., M.D., M.R.C.P.,

PHYSICIAN TO IN-PATIENTS ROYAL WATERLOO HOSPITAL

The case here recorded presents many points of interest In the first place it had to be determined whether the child was suffering from meningitis with abdominal symptoms or from abdominal symptoms with meningismus, or possibly from two separate diseases The one thing that seemed essential was to open the abdomen quickly and deal with the appendix Presumably the very severe diarrhoea was an attempt on the part of the body to get rid of some of the toxin The convulsive attacks also were apparently due to the same cause, for the operation seemed to produce an almost magical effect upon the appearance and condition of the child Personally I have never seen an attack of appendicitis commencing with severe diarrhoea and convulsions and I think that the case may be of interest to other clinicians, doubtless some surgeons have seen similar cases

Mary A— was admitted into one of my cots in the Royal Waterloo Hospital for operation on enlarged tonsils and adenoids Four days after admission the child had a sudden very severe and continuous diarrhoea for fifteen minutes The ward sister who was with the child all the time stated that she had never known a more severe one For several days afterwards constipation followed Shortly after the diarrhoea ceased general convulsions occurred the whole body seemed to be affected but especially the limbs and tongue The attacks continued for four hours before they could be checked There were twitchings of the lips tongue eyes and hands The child at first appeared to be weaker on the right side of the body but later the left side was noted to be weaker than the right The pupils became dilated the colour was first pallid but later on the child became cyanotic There was stated to be foaming at the mouth

When examined during the attacks showed nothing abnormal The child was given potassium bromide 10 grains and chloral hydrate 2 grains by the rectum one hour after the convulsions began but this had no result Later 30 grains of the bromide and 5 grains of the chloral were injected, but ultimately chloroform had to be administered to check the attacks During the night the attacks lessened and the child finally fell asleep Later on was awakened by three or four attacks of vomiting The vomit being of a greenish fluid nature

The next day when the child was examined the tongue was furred The lips showed a small trauma from the application of the forceps to the tongue on the previous night The child seemed to be in a semi-comatose condition Vomiting continued The bowels had not acted since the initial short attack of diarrhoea Urine showed the presence of acetone which possibly was due to the administration of chloroform during the attacks

The child complained of pain in the upper part of the abdomen and there was tenderness in that region No tenderness was elicited by Mr Cockell, my house physician, at this period of either iliac fossa but when he examined the child later in the day there seemed to be some tenderness in the right iliac fossa which appeared to be a little more noticeable over McBurney's point than anywhere else in this area compared with the left side I saw the case a few hours later on the same day and the child still appeared to be semi-comatose The pupils were markedly dilated, the left perhaps more so than the right Ophthalmoscopic examination was not made Photophobia was present No stiffness of the neck was elicited, nor discharge from the ear, nose, or throat The tongue was dry and furred The tonsils were distinctly enlarged, and very slightly red on the surface There was slight stiffness of the left arm and left leg compared with the right side and the left knee-jerk was also a little brisker than the right On the left side there was slight ankle clonus Babinski's sign was not obtained Kernig's sign was just present on the left side on this occasion only The abdomen was retracted tenderness was evident in the right iliac fossa in the region of McBurney's point Resistance was noted Dulness over the right iliac fossa was slightly unpitched upon light percussion there was no discharge from the vagina Examination by the rectum disclosed nothing definite The heart and lungs appeared to be normal

The diagnosis of appendicitis was made and Mr Cairns Lorrain came down to the hospital and operated immediately The appendix was found to be very long distinctly distended and acutely inflamed It was filled with hardened faeces A large number of shotty glands were seen in the mesentery The child made an uninterrupted recovery No further diarrhoea occurred, and the mental state cleared up wonderfully immediately the child came round after the operation There were no more convulsions, and all the limbs appeared to be quite normal next day

SECTION OF SURGERY.

SIR CUTHBERT WALLACE, K.C.M.G., C.B., F.R.C.S.,
President

DISCUSSION ON POST-OPERATIVE PULMONARY EMBOLISM.

OPENING PAPER

BY

P. LOCKHART-MUMMERY, F.R.C.S.,

Senior Surgeon, St Mark's Hospital for Cancer, Fistula and other Diseases of the Rectum

PULMONARY embolism may occur as the result of many different morbid conditions, but the most important and that to which I shall chiefly confine my remarks is as the after-result of an operation Pulmonary embolism by no means always fatal, and although no really reliable statistics on this point are available I should estimate that not more than one out of every ten cases of pulmonary embolism causes the death of the patient, in the remainder of the patient recovers There is little doubt that many of the cases of so-called post-operative pneumonia are in reality cases of pulmonary embolism

Pulmonary embolism may occur at any period after operation up to several weeks The most frequent period is about the eighth or ninth day, but it has occurred as early as from 24 hours of an operation and in one case as late as three weeks later Statistics are difficult to obtain, but the condition is comparatively infrequent and careful observation and records kept at most hospitals which will also of course

got out The following table gives some idea of the incidence of the condition, but shows only fatal cases

Chelsea Hospital	9 cases out of 5 406 operations
St Mark's Hospital	6 , , 7 327
St George's Hospital	12 , 11 604
St Bartholomew's Hospital	8 , 17 757
Mayo Clinic	47 63 573

This gives an incidence or rather less than one fatal case per 1 000 operations The Adelaide Hospital figures show 2 5 per cent of the post-operative deaths as due to pulmonary embolism, while St Mark's Hospital shows 5 per cent of the deaths as due to this disaster

Cases of Recovery.—When a pulmonary embolus occurs the dangerous period is during the first few minutes and as a rule if the patient can survive for ten minutes he will recover, provided that secondary pneumonia does not supervene In the non fatal cases the dyspnoea soon passes off and the pain in the chest, which is at first acute, subsides The temperature generally rises in the course of a few hours following the onset to 100° or 101° F and a cough develops in the course of the next day or two During the next few days the patient may bring up blood stained sputum Examination of the chest as a rule reveals an area of dullness and tubular breathing and sometimes friction sounds These sounds may be absent if the infarction is not near the surface and is small in area The symptoms generally pass off within a period varying from a week to ten days The distinction from ordinary pneumonia lies chiefly in the character of the onset In embolism or infarction the first symptom is always pain, and the temperature does not go up until afterwards, nor are there any previous signs of illness In pneumonia, on the other hand, the rise of temperature occurs first, as a rule, and the dyspnoea is a comparatively late symptom Also in pneumonia the temperature is much higher and the illness much longer

We may divide cases of pulmonary embolism into three categories

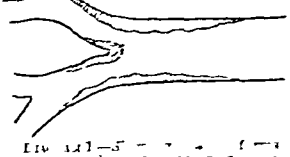
(1) Cases in which death occurs instantaneously and without premonitory symptoms

(2) Cases in which death occurs in a few minutes or hours following an acute and sudden crisis, characterized by dyspnoea and pain in the chest

(3) Cases in which the patient after a similar crisis develops signs of consolidation of part or the lung and recovers

Case of Instantaneous Death.—In such cases death takes place without warning in a few seconds A patient aged 51 at St Mark's Hospital, woke up in the morning ten days after an operation for excision of the rectum, and while speaking to the nurse, died while in the middle of a sentence There were no premonitory symptoms at all I think it is certain that such deaths as this must be due to a detached clot reaching the medulla of the brain as it seems impossible that a normal heart would stop so suddenly as the result of blocking the pulmonary artery

I have always thought that these cases must be due to pulmonary thrombosis, and a portion of the clot detaching and being swept through the pulmonary veins into the heart and thence to the brain via the carotid It is, of course obvious that a clot from the inferior vena cava could not reach the brain unless there was a patent ductus arteriosus There is, however, a specimen in the London Hospital museum showing such a condition but it could only account for a small number of the cases Valve thrombi may also account for cerebral embolism, but *post-mortem* examination has only very rarely demonstrated their presence Among the cases collected at the Mayo Clinic by Wilson 20 per cent were cases of cerebral embolism It was this fact which led me to the conclusion that primary pulmonary embolism must occur When I wrote my former paper on this subject I made a number of inquiries among pathologists as to whether they had seen cases of primary pulmonary thrombosis, but although I received answers that the condition must exist I could find no certain evidence of it I was therefore particularly pleased when I read Professor Glynn's paper (British Medical Journal, February 23rd, 1924, p 333), in which he brought forward proof that primary pulmonary thrombosis does exist He has, I think, shown beyond doubt that pulmonary thrombosis is a definite entity and thus we have a satisfactory explanation of these cases of cerebral embolism



Symptoms of Pulmonary Embolism

When the area of lung involved is small the dyspnoea is only temporary and soon passes off On the other hand, when a large area of the arterial field in the lungs is suddenly blocked the dyspnoea is very acute and accompanied by all the symptoms of great cardiac distress The dyspnoea is not due to the fact that part of the lung is put out of action, but to the strain put upon the heart by the sudden limitation of the area of pulmonary circulation It is not the sudden reduction in the breathing surface, but the obstruction to the circulation of blood between the right and left auricles which causes dyspnoea It is the sudden strain on the heart which causes death, and not the limitation of the ventilating surface This cannot be generally recognized as the usual treatment is to administer oxygen or a stimulant such as strychnine when a patient first gets signs of a pulmonary embolus This is wrong, as it is useless to kick a willing horse The heart is straining against a very sudden and serious obstruction in the arterial field from the right ventricle and it is in danger of dilating from the strain stimulants only increase this difficulty What is indicated is to try and relieve the pressure in front of the heart by dilating the vessels as far as possible and for this purpose amyl nitrite is probably the most valuable drug or in its absence atropine and morphine Should it be administered, but stimulants should be avoided

Pathology

When a portion of loose clot passes into the right side of the heart it is driven into the pulmonary artery If large enough it may block the main pulmonary artery at its bifurcation, or it may obstruct either the right or left pulmonary arteries, thus completely blocking off the blood from an entire lung Such an embolism almost certainly causes death in a few minutes from the strain thrown upon the heart If the clot is not very large it passes further into the lung and blocks one of the smaller pulmonary arteries and arrests the circulation in a cone-shaped portion of lung corresponding to the distribution of the artery concerned The condition thus produced is called an *infarct* It produces signs of localized pneumonia, but is seldom fatal It seems certain that clots cannot pass through the lung capillaries but it must be concluded that fat embolism does do so since fat emboli in the brain are well known to result from fractures of the bones and the only channel by which the fat can reach the brain is by way of the lungs Fat is a fluid and probably passes easily through the lung capillaries Emboli may lodge in the coronary arteries and one such case is included in the figures from the Mayo Clinic Such cases are probably extremely rare but will account for some of the cases of instantaneous death

It is, of course obvious that pulmonary embolism is a secondary condition and that the primary and important one from the point of view of this disease is the formation of the primary intravascular clot It is only in a few cases that we have any evidence of the situation of the primary clot When such evidence is available it generally shows that the primary clot is in the internal or external iliac veins or at the point when they join to form the inferior vena cava (see Diagram 1)

[illegible]

In some cases the inferior vena cava [illegible] with clot Many writers have assumed that originated at or near the area of [illegible] of this has been disproved [illegible]

In connection with [illegible] to remember [illegible]

for instance, said that he believed ligaturing portions of the omentum by transfixion was liable to result in embolism, forgetting that the omental veins drain into the liver (see Diagram 2)

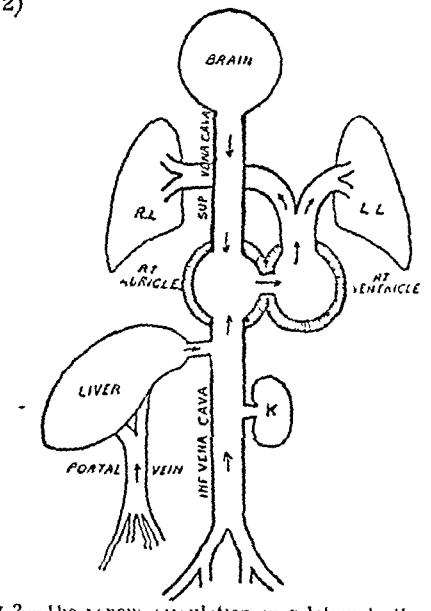


Diagram 2.—The venous circulation in relation to the formation of pulmonary embolism

The following table of fatal cases, taken from the Mayo Clinic, showing the operations most commonly followed by pulmonary embolism, is of particular interest

Site of operation	No. of deaths
Thyroid	2
Mouth	1
Stomach	3
Gall bladder	9
Small intestine	1
Appendix	4
Colon and rectum	5
Hernia	5
Kidney	1
Prostate	4
Uterus and appendages	10

N.B.—The operations in italics were in areas drained by the portal vein

The embolus was—

Pulmonary in	36 cases
Cerebral in	10 ,,
Coronary in	1 case

You will notice that a large proportion of the operations were performed upon parts of the alimentary canal which drain into the portal veins. In fact operations upon the gall bladder, stomach, and appendix, all of which have their veins draining into the portal veins, account for over half of the cases. Yet the embolus which caused death passed into the right auricle and plugged the pulmonary artery. The clot therefore did not form in the operation area, but almost certainly in the iliac veins or vena cava.

The obvious conclusion from these facts is that the primary clot forms in the vena cava, or its branches, quite irrespective of the operation area, and is due to stasis in the great venous trunks rather than to any injury of contributory veins. Another important point is the marked difference as regards liability to post-operative embolism between the upper and lower parts of the body. Any study of cases of post-operative pulmonary embolism will show that in almost all the cases the operation has been upon the abdomen and lower limbs. Thus in only 3 out of 47 cases at the Mayo Clinic was the operation area in the upper part of the trunk, while in 9 cases at the Ad Lude Hospital all were due to lesions in the lower part of the trunk.

Operations on the breast, head, neck, and arms are common enough, and yet are very rarely followed by pulmonary embolism. Why is this? I believe the explanation to be that operations upon the upper part of the body do not tend to cause such a degree of venous stasis in the veins as operations upon the abdomen. Venous stasis cannot occur in the superior vena cava as a free flow of blood through the brain is essential to life. The brain is the controlling factor, and the vaso-motor centre will starve the rest of the circulation if necessary in order to maintain an adequate circulation through the coronaries and superior vena cava.

The fact that operations upon the pelvic organs more frequently result in pulmonary embolism than operations on other parts has called for many different theories in explanation. It has been suggested that pelvic operations are more liable to result in injury to large veins. It has also been pointed out that there are no valves in the ovarian veins, but there is no evidence that valves, even when present, have any influence in arresting the spread of thrombosis. A much more reasonable explanation, it seems to me, is that operations upon the pelvic organs tend to a greater degree of immobility both during and after the operation than operations elsewhere. The position of the patient during most pelvic operations, and the presence of retractors and packs in the pelvis, must tend to arrest the circulation in the inferior vena cava, both by direct pressure and by interfering with the action of the diaphragm, which, as you know, is most important in aiding the flow of blood in the abdominal veins.

As I have already pointed out, operations upon the areas of the abdomen drained by the portal vein account for more cases of pulmonary embolism than operations on the pelvic organs (see Diagram 1), and it cannot be suggested that injury to the branches of the portal vein can cause a pulmonary embolism.

A further argument in favour of venous stasis as the chief cause of post-operative pulmonary embolism is that we find it is more liable to occur in patients whose circulation is poor—as, for instance, in cases where there has been *loss of blood*, in anæmic persons, and those suffering from chronic toxæmia. The conditions predisposing to venous stasis are immobility of the lower part of the body in a constrained position, a poor circulation such as is present in a patient with anæmia, and an open abdomen which will do away with the effect of respiration upon the abdominal contents. If we add to these the pressure of packs and retractors in the abdomen, and a certain degree of haemorrhage, it is not unlikely that a considerable degree of stasis occurs in the inferior vena cava and iliac veins during operations upon the pelvic and abdominal organs.

When fluid is flowing through a channel or pipe the stream is fastest in the centre of the channel and slowest at the sides. This can be observed in any river, and is equally true of the inferior vena cava. If for any reason the flow is considerably slowed there may be complete stagnation of the flow against the walls of the channel, although a fair current is still maintained in the centre (see Diagram 3). This stagnation will be accentuated at places where side channels come in, as there would be a tendency to the formation of back eddies at the corners. This is what I conceive occurs in the inferior vena cava during certain operations.

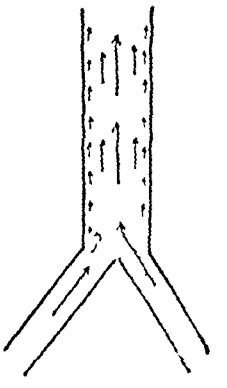

Diagram 2.—Shows how the current is slowed near the wall of the inferior vena cava.

If we grant that venous stasis is the most important predisposing cause of pulmonary embolism, it will explain many of the facts. It explains why abdominal and pelvic operations account for the vast majority of cases. It explains why patients with anæmia or with abnormalities of the blood or circulation are more liable to pulmonary embolism. It also explains why children do not appear to suffer from embolism after operation. It is rare in children, no doubt owing to their more active circulation, which does not allow of stasis in the veins. Children suffer from pneumonia after operations, but it is always of the bronchopneumonic type.

Sepsis

There is a very prevalent belief that embolism is due to sepsis. I cannot accept this belief. The majority of cases followed by pulmonary embolism are clean cases, and there is no evidence of sepsis at all. Beer, in his review of 6,825 operations, came to the conclusion that sepsis cannot be the cause of thrombosis. This is confirmed by the figures of the Chelsea Hospital, which only one case of mine was definitely septic.

surgeons say that embolism results from a mild form of sepsis unaccompanied by the breaking down of the wound This surely, is merely begging the facts If sepsis is the cause of the condition the secondary focus caused by the embolus becoming arrested should become septic and then would have a pyaemia This is, however, not the case true, a secondary pneumonia often develops but this is not as a rule a septic pneumonia but a pneumonia due to the ordinary pneumococcus having been able to obtain entry to the damaged lung Moreover the time at which the embolus occurs does not fit in with its being due to sepsis Embolism sometimes occurs within a few hours after operation on which would seem to be altogether too soon On the other hand in not a few cases it does not occur for three weeks, or even longer I have notes of one case in which an infarct formed three weeks after a simple laparotomy which had healed by first intention, of another case in which a fatal embolism occurred six weeks after a normal confinement and Wilson records a fatal case of embolism nine weeks after operation We have to remember that septic wounds are usually more painful than non septic wounds so that the patient probably keeps much quieter Further the patient's general health is lowered and blood changes probably occur which encourage the formation of intravascular clotting In these ways I believe sepsis is a contributory cause, but I am certain it is not the direct cause

It seems at present impossible to determine what if any is the exact relationship between sepsis in the wound and post-operative embolism and infarction There is no proof that the presence of septic organisms or their toxins in the blood induces intravascular clotting and, on the other hand septic diseases which are not the result of wounds such as whitlows and abscesses, sapraemia scarlet fever etc, are not complicated by emboli and infarcts We are however still very much in the dark as regards the exact morbid physiology of phlebitis

A further argument against sepsis being the cause of the condition is that it will not account for cases of embolism following such operations as simple laparotomy, hernia interval operation for appendicitis, or operations for piles Moreover it will not account for the cases of crossed thrombosis It is not uncommon to find thrombosis occur for instance, in the left saphena vein or femoral vein after an operation on the right side, or vice versa On looking through the records of cases of embolism one is struck by the fact that in quite a number of cases thrombosis in the leg has been present, either before the occurrence of the embolus or afterwards, and that this thrombosis is not always on the same side as the operation where the latter is unilateral

When a thrombosis occurs in one of the veins of the lower limbs it is naturally detected, but obviously if thrombosis occurs in one of the pelvic or abdominal veins it is not likely that this could be detected unless it is able to cause such an arrest of the circulation as to produce swelling in one of the lower limbs, or other signs of inadequate venous circulation in the parts drained by that vein Quite extensive thrombosis may take place within the abdomen without producing any obvious signs of its presence in a recumbent patient It is true that it would almost certainly cause pain, as pain is always a first symptom of thrombosis but as the pain would be referred to some part of the abdomen its real cause may easily be overlooked, in fact in looking through the notes of some of the cases of embolism I find that in several it is stated that vague pains in the abdomen have been complained of by the patient before the occurrence of the embolism

It seems to me that all the evidence points to venous stasis in the large veins of the abdomen as the chief factor in producing pulmonary embolism after operation but when we turn to the experimental side of the subject we come up against a serious difficulty Venous stasis cannot be the only cause as there is no evidence that mere recumbency or lack of movement will result in thrombosis apart from operation Embolism does not occur after rest cures or in paralysed persons who have lain in bed for months, or even years Obviously were mere venous stasis the cause we should be liable to get thrombosis and embolism as the result of normal sleep The physiological proof that mere venous stasis does not cause thrombosis is of very ancient date, over one hundred years ago Hunter proved that intravascular clotting does not take place in an intact vein even when both ends are ligatured His now famous "living test tube" experiment was made by tying at both ends six inches of the jugular vein of a horse He found that the blood was still fluid at the end of six days

The physiologists have shown that in order to produce clotting of the blood a substance called thrombokinase must be present in contact with it This substance, thrombokinase, is present in the blood, but is found in varying quantities in all the other tissues of the body and a certain quantity is liberated whenever a wound is made It is the contact of the escaping blood with the thrombokinase present in the wound tissues that determines the formation of the clot which seals up the vessels after a cut has been made The change which takes place to produce a clot when thrombokinase comes into contact with blood may be expressed as follows

Thrombokinase + a calcium ion + thrombogen (normally present in the blood) = thrombin
Thrombin + fibrinogen (present in the blood) produce fibrin (clot)

Thrombokinase introduced into a vein produces intravascular clotting if the blood is stationary but apparently fails to do so if the circulation is active

Recently Professor Collingwood has shown that intravascular clotting does not follow the intravenous injection of thrombin even when injected in relatively enormous quantities, *if the blood is in a condition of movement or circulation*, although the amount or thrombin injected is actually sufficient to clot every drop in the animal's body if removed from the vessels

It has been stated that increasing the calcium content of the blood would cause intravascular clotting, but more recent work has proved this not to be the case The amount of calcium present in the blood is the maximum required, and the addition of more calcium tends to reduce the clotting capacity rather than to increase it

It would seem, therefore that before a thrombus can occur two factors must be present

(1) A certain amount of thrombokinase derived from the tissues and liberated by the wound must be present in the blood but the amount would appear to be very slight

(2) There must be venous stasis

Neither factor alone can produce a thrombus but both must be present at the same time (N B —The reason why intravascular clotting occurs when a vein is damaged or inflamed, is that thrombokinase is liberated at the point where the intima is damaged)

The sequence of events seems to be somewhat as follows As the result of the wound thrombokinase is liberated from the tissues and passes via the lymph stream into the circulation (or possibly passes direct into the vein) this enables a clot to form in those veins in which the blood is for the time being stagnant or nearly so

Time when the Thrombus Occurs —We have in any given case of pulmonary embolism only got evidence of the time when the clot separates and sticks in the pulmonary artery obviously the thrombus which formed this clot, or from which it has broken off, must have formed much earlier but there is no means of ascertaining when this occurs It seems to me that everything points to the conclusion that the original thrombus formed on the walls of the veins during the operation and that it spreads during the period of quiescence immediately following the operation The danger period is in fact the time of operation and at any period after this from a few hours up to many weeks a portion may become detached and produce an embolus, the subsequent result depending on the size of the embolus the part of the circulation in which it starts and where it becomes arrested

My theory of pulmonary embolism is that the operation predisposes to the condition in two ways it results in the liberation into the circulation of thrombokinase from the cut surfaces, and at the same time tends to produce clot stasis near the walls of the great veins If these two conditions occur in a sufficient degree a thrombus forms and the train is laid for a pulmonary embolism a late

period I do not think that sepsis is at all an important factor, if it is a factor at all I think for once sepsis may be found not guilty

Treatment

At present there is no known means of ascertaining when a thrombus has formed in the great veins and much less is there any means of treating it We might, it is true, take steps to reduce the coagulability of the blood of the patient previous to operation, but I do not think that this would meet with the approval of the surgeons as it would be liable to result in equally serious disasters of another kind

Trendelenburg has suggested operating in order to remove the thrombus from the pulmonary artery, and there are records of this being done, but it does not seem sound, as patients who have survived a pulmonary embolism long enough to undergo an operation will probably recover anyway It is to prevention rather than cure that we must look if we want to get rid of the mortality after operations from pulmonary embolism

The present methods of anæsthesia, which include a preliminary injection of morphine probably tend to encourage thrombosis by slowing the blood stream during the dangerous period This possibly explains the greater frequency of cases of embolism during the last ten years, as compared with the time when most patients were given gas and ether, with consequent vomiting as soon as they had left the table

The best method of preventing patients from getting post-operative thrombosis does not consist in altering the technique of operations, but rather in altering the methods of preparation and of after-treatment Preliminary purgation of the patient should be entirely abolished, if necessary it should be carried out five or six days before operation The practice of starving the patient both before and after operation should be discontinued The supply of proper mattresses on the tops of operating tables, and the prevention of the patient assuming a constrained position during the operation which would cause pressure upon the veins, are points requiring greater attention The frequency of embolism after gynæcological and gall-bladder operations is possibly attributable to the unnatural positions in which the patients are placed I think we should attach more importance to the comfort of the patient on the operating table than we do at present The patient being under an anæsthetic we not unnaturally consider our own comfort and the accessibility of the operation area in placing the patient on the operating table, and do not think that the patient may for an hour or more be in a most constrained position, which will embarrass the circulation in the lower limbs and pelvic veins

Although the subject is such a difficult one and the means of preventing embolism are so uncertain, it is, I think, a great thing that surgeons have at last begun to try and find out the cause of the condition and to inquire how they may prevent this dreadful complication The fact that they are no longer satisfied to accept pulmonary embolism as an act of God, but are anxious to try and ascertain what fault of their own it is that causes it, is a great step in the right direction and I feel sure that the number of cases of pulmonary embolism in the next ten years will be much reduced

Discussion

Sir Charles Gordon Watson (London) said that with the great progress in surgical technique post-operative risks had been greatly diminished and in the up-to-date clinic terminations were carried out the risk of sepsis The abolition of drastic purgation and starvation before operation, the introduction of gas-oxygen anæsthesia, gentler handling of the tissues and the revival of whole-blood transfusion had reduced the risks from shock to a minimum Yet the bogey of embolism with its tragic suddenness remained unchecked, and if they might draw conclusions from limited statistics, was actually on the increase

This risk, as Mr Lockhart-Mummery had stated, was put as at more than 1 in 1,000 operations A rough index of the incidence might be gathered from the following figures, obtained from the surgical necropsy records at St Bartholomew's

1912 13 14 Operations, 10,604 necropsies, 591 Deaths from pulmonary embolism, 3 = 0·5 per cent Average age, 52
1919 20 21 Operations, 9,558 necropsies 538 Deaths from pulmonary embolism 9 = 1·7 per cent Average age 60
1922 23 Operations, 8,839 necropsies, 358 Deaths from pulmonary embolism, 10 = 2·79 per cent
Total operations, 29,001 Deaths from pulmonary embolism, 22

These figures indicated that at St Bartholomew's Hospital pulmonary embolism was on the increase, but the series was too small for general conclusions to be drawn Mr Lockhart-Mummery, however, had arrived at a similar conclusion from his study of collected cases

He thought it would be helpful to draw a distinction between massive pulmonary embolism and pulmonary infarction, he did not propose to discuss pulmonary thrombosis Pulmonary infarction followed the detachment of a small particle of clot, and was liable to be multiple and recurrent Pulmonary embolism could only occur when a massive clot was detached and became impacted in the main pulmonary artery When thrombosis occurred as a result of active inflammation, the clot became firmly fixed to the vessel wall, and was not likely to become detached *en bloc* except in the very early stages If suppuration began the clot would soften, and fragments were then liable to be detached and carried off into the blood stream, causing infarction Detachment of a large, recently formed, firm clot would seem to be less likely to occur when the wall of the vein was inflamed than when the wall was relatively smooth and a clot formed as the result of stagnation rather than inflammation

He agreed with Mr Lockhart-Mummery that in most instances of pulmonary embolism passive clotting had occurred in the large veins in the pelvis under certain favourable conditions during operation or quite early after operation These clots remained for some time loosely attached to the wall of the vein, and were easily detached by sudden movement, active muscular contraction, or sudden acceleration of the heart's action The fifth to the tenth day was the most likely period for this accident to occur Though the majority of these emboli could be traced to an origin in the iliac or femoral veins, others had their origin in the right auricular appendix In most instances, prior to a massive embolism, thrombosis had been neither observed nor suspected Phlebitis, with pain and swelling of the limb, seldom preceded this sudden catastrophe In the great majority of the cases there was no preceding rise of temperature, nor was there any feature in the clinical course to sound a note of warning of an impending disaster On the other hand, in many cases of pulmonary infarction the post-operative pulse, temperature, and respiration often failed to settle down to normal The surgeon might recognize that, without any definite explanation, the patient was not quite so fit as he ought to be, even though there was no evidence of phlebitis In many instances when pulmonary infarction occurred a low grade of inflammation in connexion with the wound or with phlebitis preceded the onset

Excluding post-operative infection, what were the controlling factors in post-operative thrombosis? Thrombokinase, as Mr Lockhart-Mummery suggested, when released at operation and absorbed into the blood might be the exciting factor in thrombosis under favourable conditions If they assumed that thrombosis might occur in a large venous current when thrombokinase was present in the blood, what other factors, if any, were essential? Was trauma essential? Though, as Mr Lockhart-Mummery had pointed out, Hunter failed to secure intravascular clotting in an intact vein, it might be quite possible for a thrombus starting in a small vein ligatured, crushed, traumatized, twisted, or torn during operation to extend and involve a healthy vein Might not injury to the deep epigastric veins—for example, by retractors—give rise to thrombus which might spread to the external iliac vein, or injury to uterine vein excite a thrombosis which might spread to the internal iliac? Unnecessary injury to veins in the abdominal wall during an operation might be cause for

violent stretching and undue pressure with powerful retractors Transfixion of the pedicle containing large veins, as in the broad ligament, clamping of structures in bulk as opposed to clamping of individual vessels and twisting of veins were points worthy of consideration in this respect also The application of forceps, followed by the ligaturing of small venous branches close up to their junction with a large vessel, might result in injury to the wall of the main vessel beyond the site of ligature The presence of a haematoma in the abdominal wall might be the cause of thrombosis in one of the epigastric veins In a fatal case of pulmonary embolism at St Bartholomew's after an operation for hernia, a haemorrhage in the inguinal area had produced pressure on and thrombosis in the femoral vein Haemorrhage into the tissues of the broad ligament or the mesentery might, by producing pressure on the iliac veins, start a thrombosis When a needle pierced or wounded a vessel, or when the lining of a vessel was injured by torsion, if a ligature was not applied above the point of injury thrombosis might easily occur in a sluggish blood stream Septic pulmonary infarction was a very common complication of war wounds and one of the common causes of a fatal issue, but massive pulmonary embolism was by no means common The fact that nearly all wounds were primarily infected and phlebitis was a very common complication while massive pulmonary embolism was rare, was presumptive evidence that sepsis played an unimportant part in pulmonary embolism as distinct from infarction

The factors responsible for a sluggish circulation might be grouped under the following headings

(A) *Loss of Fluid*—(1) Before operation by purging (2) during operation by haemorrhage and sweating (3) after operation by vomiting and the limitation of fluid by the mouth or rectum

(B) *Loss of Blood Pressure*—(1) Through post operative shock (2) prolonged anaesthesia especially chloroform (3) by injection of morphine before and after operation, (4) by a recumbent fixed position after operation with a minimum of movement and muscular action of the lower extremities (5) by diminished respiratory effort during convalescence in recumbency

(C) *The effect of posture during operation* on the return of blood through the inferior vena cava

It was difficult, if not impossible, to show to what extent if any the factors enumerated under these headings might be contributory causes, but it was clear that all of them were more or less under the control of the surgeon, and it seemed at least reasonable to argue that much might be done on these lines to prevent the onset of passive thrombosis For the past four years he had had respiratory exercises followed by massage carried out in his wards after abdominal operations, and he allowed patients to *move about in bed and to get up very much earlier than he* used to do He had no doubt that preliminary and excessive purging immediately prior to operation was a factor in the production of post-operative shock. Many a gallant soldier *must owe his life to the fact that he was operated on in* a casualty clearing station where there was neither time nor inclination to purge him!

So far as the posture at operation was concerned it was *interesting to note that operations on the pelvic viscera* were responsible for more pulmonary embolisms than any other class, and that gall bladder operations stood very high in the list The following questions might be asked in this connexion Did the *constrained and tilted position* of the spine often adopted during operations on the gall bladder, kink the inferior vena cava and obstruct the return of blood? Did the high Trendelenburg position, by upsetting *the normal position of the heart, act in a similar manner* causing undue pressure of the ventricles on the auricles and so on the inferior vena cava, and did not this position often produce pressure on the popliteal vein?

The clinical picture of pulmonary embolism was too distinctive and dramatic to escape recognition during life but the embolus might sometimes escape detection after death if the heart was severed from the lung before the pulmonary artery had been opened He had seen an embolus drop out in this manner When death occurred from pulmonary embolism an *ante-mortem* laminated clot was found usually coiled up at the pulmonary inlet and *projecting into one or both main branches* The surface of the clot when inspected closely had a finely granular appearance, it was firm to the touch and showed no sign of breaking down It was often branched when it arose from the internal iliac If the pulmonary artery was opened with the heart *in situ* the embolus could usually be removed intact and might be many inches long when unravelled On one occasion when surgical registrar at St Bartholomew's he had found in a case of fracture of the leg a firm clot in the internal iliac which came to an abrupt and irregular termination at its junction with the external iliac He removed a curled up embolus from the pulmonary artery, and found that it accurately fitted on to the existing clot and had obviously been broken off by the current of blood from the external iliac vein In that case, there was no femoral phlebitis or thrombosis in relation to the fracture

The lungs of a patient who died of sudden pulmonary embolism showed oedema and congestion Such congestion would be more pronounced in a lung when the artery was completely blocked than when partly blocked and would vary in intensity with the duration of time after the block had occurred Under normal conditions the pressure on the outside of the capillaries in the lung was negative When a forced inspiration occurred after blocking of the pulmonary artery, it was probable that blood was sucked back from the left auricle via the pulmonary veins into the pulmonary capillaries and stagnated there in the absence of any flow *of blood from the pulmonary artery In that way much* blood was withdrawn from the general circulation, an important factor in the shock which occurred Signs of infarction were absent unless a fatal embolism had followed on a previous infarction

The right heart even in sudden death under these conditions was found dilated, and there was little doubt, as Mr Lockhart-Mummery had stated that the main cause of death was heart failure from dilatation of the right ventricle though shock was an important additional factor One element in the shock was probably the withdrawal of a considerable volume of blood from the systemic circulation by stagnation in the pulmonary area and another was the fear of impending death so commonly noted in these cases

With regard to prophylaxis Sir C Gordon-Watson remarked that by gentleness in operating they might avoid unnecessary trauma and eliminate an important excitant cause, by the careful control of haemorrhage they might check the absorption of thrombokinase and avoid thrombosis due to pressure from a haematoma If they did not reduce a patient to pulp before operation, allow him to bleed at operation, or fail to be generous with fluid after they should at any rate not impoverish his blood supply If they avoided constrained positions at operation and fixed positions after it they stimulated respiratory and muscular effort during convalescence, they should do no harm and would perhaps avoid disaster

Once an embolism had occurred he was in thorough agreement with Mr Lockhart Mummery on the importance of relieving the great strain on the heart with amyl nitrite and combating the shock by morphine He was present on one occasion in a private house within a few minutes of the onset of an attack With the aid of morphine and oxygen (amyl nitrite was not available) he reduced the mental distress and lowered down both the heart and respiration but he could not overcome the asphyxia or change the ashen grey hue which was a combination of the pallor of shock with the blue of deficient oxygenation nor could he prevent the ultimate heart failure which occurred just over two hours after the onset On another occasion in a case of abdomino-perineal excision, the house-surgeon of St Mark's Hospital kept the patient going with continuous oxygen from 11 a m to 7 o clock next morning It was unusual for a patient to survive so long and not recover and he thought it was probable that had morphine and amyl nitrite been employed the heart might have been equal to the strain while the pulmonary circulation was becoming adjusted to the altered condition The late Professor Bainbridge, shortly before his death, had commenced work on this subject and had obtained some interesting results from the ligature of one pulmonary artery in the cat Was it too much to ask of the British Medical Association to devote a sum of money to research in this subject, which had long baffled medical science

Professor J Shaw Dunn (Manchester) said that in his general survey of the subject Mr Lockhart-Mummery had shown that, as a sequel to modern operative procedures, pulmonary embolism was a comparatively infrequent occurrence, and he had also offered some evidence that even when it did occur it was not usually attended by a fatal result In agreement with this it might be said that in the *post-mortem* room pulmonary embolism was relatively seldom found to be the cause of post-operative deaths Still, such cases did appear from time to time, and the circumstances of their occurrence as revealed in the clinical notes were usually of a sufficiently tragic character to excite considerable interest and to lead to an intimate inquiry into their causation If attention was restricted to immediately fatal cases the morbid appearances were found to be fairly uniform an elongated mass of dark-red clot was found coiled up and impacted in the bifurcation of the main pulmonary artery or in one of the main branches When this was being looked for it was essential to open up the right ventricle and pulmonary artery before the thoracic organs were disturbed in any way, for in some instances the clot was sufficiently loosely held to slip out from its significant situation, and thus left the nature of the condition in doubt In a typical example of the kind the cause of death was not in question, for there was ample evidence of a sudden arrest of the circulation as a whole

The important question that did arise, as Mr Lockhart-Mummery had pointed out, was that of the original site of the thrombus Having in mind the importance of circulatory stasis and of damage of vascular endothelium in the promotion of thrombosis, it was not unnatural that this site should first be looked for in some large vein near the operation area, where tissues had been more or less injured and vessels had probably been tied In what proportion of instances the thrombus did come from this area it was impossible to say, but in his own experience of seven or eight cases it had always been traced thither when sufficient care had been taken in dissection of the wound When the larger veins, of a size which could have accommodated the fatal embolus, had been opened up they had been found to be empty, this was to be expected, for if the thrombus had remained *in situ* the patient would not have died of pulmonary embolism But at some point on the wall of the large vessel, or often protruding into it from the opening of a small tributary, there might be found a tiny tag of formed thrombus, the broken end from which the large mass had become detached Further examination of small veins might readily reveal a greater extent of thrombus still *in situ*, but sometimes the amount remaining was not large

The next question of vital importance was, of course, why massive thrombosis of this type occurred in some cases and not in others To this question it was evident that the experience of different observers had led to varying answers Mr Lockhart-Mummery regarded the part played by sepsis as insignificant, but with that conclusion there must be many surgeons and pathologists alike, who would fundamentally disagree In support of this statement reference might be made to a discussion by the North of England Obstetrical and Gynæcological Society of a paper by Professor Glynn on pulmonary embolism and thrombosis[1] Considering for a moment the condition of frankly declared septic infections one could not but recognize how frequently thrombosis was an associated phenomenon there was the familiar development of cerebral sinus thrombosis in otitis media where a suppurative focus impinged directly on a large vessel channel the thrombosis of the veins in relation to septic uterine disorders, and of the portal vein to appendicitis or other septic focus in the intestinal tract Not only did sepsis have as one of its serious consequences the development of local thrombi, but the general poisoning of the system might result in the formation of *ante-mortem* clots in the heart itself, as was commonly seen at the termination of pneumonias, but also in surgical forms of septic infection

It was no doubt perfectly true that in cases of post-operative pulmonary embolism there was not as a rule gross and frankly declared septic infection of the surgical wound, but infection of some degree could frequently be found—so frequently that one was inclined to believe it invariable In illustration of the type and extent of wound infection which could determine fatal embolism it might be permissible to refer briefly to two cases

Case I—A woman, aged 69 years, had the left mamma amputated, and after the operation appeared to be making an entirely satisfactory recovery When allowed to sit up twelve days after the operation she fell back and died in a few seconds At the *post mortem* examination the superficial wound appeared quite satisfactory, the skin incision having healed A large elongated cylindrical thrombus was found coiled up in the bifurcation of the main pulmonary artery, completely blocking both branches The imprint of valves was clearly visible on this thrombus leaving no doubt that it had been transported from a vein The left subclavian vein when slit up was found patent and normal, except that a small ragged mass of reddish-yellow thrombus was found adherent to its wall at the orifice of a branch which entered from the region of the mammary wound This small vein contained similar solid material in the rest of its extent When the innominate vein was opened up it was found to be dry and healing anteriorly, but in the posterior part the tissues were œdematous and slightly turbid fluid exuded from them on pressure Pools of morphonuclear leucocytes and streptococci were found in this fluid on bacteriological examination

Case II—A young woman had varicose veins removed from the right leg and thigh by dissection The long skin wound was completely closed by sutures and healing appeared to proceed normally, but the patient died suddenly about a week after the operation After death a coiled embolus was found in the pulmonary artery In examination of the operation wound after the operation the healing conditions in the skin and subcutaneous tissues, and it appeared as if for once some other explanation than local sepsis must be sought to account for the fatal embolism It was only when a close inspection was made of the stump of the internal saphenous vein that the nature of the fatal embolism was found to be bathed in sanious fluid in which streptococci and polymorph leucocytes were subsequently demonstrable by films On the inner aspect of the venous stump there was present a thin, ragged layer of thrombus from which, no doubt, the embolus had broken away The recognizable septic focus was in this case extremely limited, being less in size than a pea, but it occurred just on the wall of a large vein, where it was most liable to produce a serious result

In other cases of the same type to which reference might be made the evidences of wound infection were usually rather more obvious though never very advanced, and the impression that remained from a consideration of all of them was that all cases of post-operative pulmonary embolism were suspect of being derived from sepsis unless cleared of this suspicion by a most thorough investigation

Professor Ernest Glynn, associated with Dr Maurice Cohen, detailed the evidence that primary pulmonary thrombosis was a cause of sudden death, and was more frequent than pulmonary embolism Stasis and mild sepsis were two main factors in the production of the thrombosis Stasis could be diminished by post-operative exercises, including deep breathing

Mr James Berry (London) confined his remarks to post-operative pulmonary embolism He thought that this was due in the main to the bad practice, still much too common, of keeping patients quite quiet in bed for days or weeks after operation In the case of operations upon parts above the diaphragm, such as those for carcinoma of the tongue and large operations of all kinds upon the neck, there were but very few patients who could not with advantage be got out of bed on the first, or at latest on the second, day after operation This had been his practice for many years, and he had not yet seen embolism after any such operation Nevertheless, he well remembered being solemnly warned some twenty-five years ago by a senior colleague that this practice was highly dangerous, and that it would result in the occurrence of embolism this being the view that was generally held at the time In the case of operations on the abdomen pelvis and lower limbs it was, of course, impracticable to get the patient out of bed quite so early Nevertheless, much might be

[1] Brit Med J, February 23rd and April 19th, 1912, pp 353 and 712

done in such cases to prevent the occurrence of embolism by letting the patient sit up in bed at a very early stage, by encouraging him to turn from side to side and to move his legs and arms (unless actually the seat of operation) Such treatment prevented stasis of blood in the larger veins and the dangerous formation of large passive clots, which in turn led to embolism

He could not remember having had more than one fatal case of embolism after this class of operation This was the case of a woman operated upon for varicose veins and who had erroneously, been kept in bed much too long She died quite suddenly of embolism as she was leaving the hospital Another contributory cause of embolism, especially after pelvic operations was, in his opinion, the blind transfixion of tissues with ligatures Ligatures passed in this way could easily be made inadvertently to transfix pathologically enlarged veins, and, without causing noticeable haemorrhage, create a focus for the subsequent formation of a clot, thus leading to embolism

Mr Harold Burrows (Portsmouth) referred to two cases in which pulmonary embolism followed thrombosis of varicose veins in the calf of the leg In both instances the patients had been treated by splinting and absolute immobility and the occurrence of fatal embolism in these conditions seemed to lend support to the suggestion that strain played a part in the causation of the thrombosis

Sir Cuthbert Wallace (London) thought that Professor Glynn had rendered great service in bringing forward the question of the part played by pulmonary thrombosis apart from embolism As regards embolism, this was only a catastrophe in the course of a fatal common disease—namely, systemic thrombosis If a proper perspective was to be got, all cases of thrombosis must be tabulated and the number of dislodgements of the clot enumerated In addition the investigation must not be confined to surgeons but must be carried out by all branches of the profession, so that all cases of thrombosis and embolism would be put on record

Professor G E Gask (London) stated that the action of the Council in choosing this subject had been justified It had produced a most valuable discussion of an obscure condition He gathered that the surgeons were of the opinion that sepsis would not explain all the cases and the pathologists were of a different opinion He complimented Professor Glynn, who had introduced a mass of new and original work of the greatest value

Mr Lockhart-Mummery, replying, said he had not meant to suggest that sepsis might not be a cause of thrombosis, but that it was not an essential cause One speaker had argued that in a large number of cases there was evidence of a slight rise in temperature to 99° or 100° previous to the onset of a pulmonary embolism, and had considered that this was evidence of epsis Mr Lockhart-Mummery did not agree, since it was a well known fact that thrombosis itself was almost invariably associated with a slight rise of temperature Even haematomata caused rise of temperature, and it was not, therefore, safe to argue that in such circumstances a rise of temperature indicated sepsis Even when definite evidence of sepsis was present it did not necessarily follow that thrombosis was due to the sepsis On the other hand, in quite a considerable number of cases of thrombosis there was no evidence of any kind of sepsis He would like to congratulate Professor Glynn on his paper in which he had undoubtedly proved that primary pulmonary thrombosis did occur and was an important factor This was a valuable contribution to their knowledge of this difficult subject If surgeons all over the country would make a point of carefully recording all cases of pulmonary embolism with careful records of the microscopical and macroscopical findings, it would be a great help in elucidating the problem With regard to treatment he was pleased to see that there was a general agreement that constrained positions on the operating table and lack of movement after operations were important contributing factors in producing pulmonary embolism

MEDICAL, SURGICAL, OBSTETRICAL

FATAL FOOD POISONING DUE TO BACILLUS SUIPESTIFER B

The following notes of a fatal case of bacterial food poisoning seem worthy of record

On June 8th 1924 a man aged 43 had for breakfast a pork chop and bacon for dinner some pig's tongue beet and potatoes and for tea some cake and bread and butter The same evening he had a drinking bout during the course of which he is believed to have eaten some periwinkles favoured in the Black Country as a reputed preventive of alcoholic intoxication On June 9th he remained in bed he did not eat anything but drank a bottle of beer and some tap water during the afternoon he complained of slight diarrhoea On the next day the diarrhoea got steadily worse and he occasionally vomited By noon on June 11th the patient was seriously ill with slight abdominal pain and constant purging some abdominal distension was present the temperature was subnormal and the pulse rate a little over 90 The motions were yellowish and slimy but no blood was seen in them On the following morning he got up and had a wash he then returned to bed was very restless all day and complained of severe tenesmus and constant purging his mental condition however was quite clear At 9.30 p m he was *in extremis* and at 10 15 he died

At the necropsy signs of septicaemia were present The small and large intestines were acutely congested fatty degeneration was present in the liver and cloudy swelling in the spleen and kidney At the base of the left lung there was a small patch of pneumonia Samples from the heart blood gall bladder spleen and small and large intestines were sent to the laboratory for investigation and Dr Herbert Henry isolated from all the specimens the *Bacillus suipestifer* B

The *Bacillus suipestifer* (*aertrycl*), or the hog cholera bacillus, occurs in the intestines of normal pigs and may cause meat poisoning Pork and preparations made from it become infected by contamination with infected pig's excreta The bacillus may also be found in mutton and beef Meat from healthy animals which has been in contact with that from diseased animals may become infected It has been noted that the bacteria or their toxins may be distributed unevenly in the meat eaten, so that one person consuming the meat may be made very ill while others eating it escape infection The disease varies much in severity, fatal results are uncommon Children old people and debilitated persons are the most vulnerable In this case the public health officials made careful inquiry but were unable to obtain any remnants of food for examination as it had all been eaten No other cases of illness occurred in the house

West Bromwich. DUDLEY GILL, M B, Ch B, D P H

LYMPHATICOSTOMY IN PERITONITIS *

Normal physiological processes do not occur in disease and this fact dominated the experimental work which laid the foundation for the operation of lymphaticostomy The disease was set up first and the processes actually occurring in the disease studied The findings were that septic absorption in peritonitis occurs to a lethal degree through the lymphatics to the thoracic duct This absorption is from the peritoneal cavity and the lumen of the bowel through the lymphatics proper and the lacteal There is a suction force on the thoracic duct due to the venous blood passing the opening of the duct similar to that created by the Sprengel pump *plus* a negative pressure which may be present—and probably is always present in peritonitis—in the large veins near the heart This suction increases with the rapidity of the heart beat and with the dehydration of the blood, which tend to produce a greater negative pressure in the large vein This would help to explain the beneficial action of large quantities of saline and the giving of morphine by which the blood vessels are kept filled and the heart action lowered

In lymphaticostomy the ligature cuts off this suction, and when the duct is opened there is a flow of lymph The duct does not become distended when ligated and the lymph flow is less than one would expect from observing the leak through the duct before ligating and opening The duct

* Slightly curtailed for publication.

is transparent, and, according to the character of the fluid, one sees a translucent or a milky white cord when lymph or chyle is flowing, and to the experienced eye it is unmistakable. In peritonitis, however, the fluid may be bloody and the duct may resemble a vein and must then be distinguished by its position. In the experiments I noted that the introduction of tap water into the intestine through a duodenal tube produced an immediate rapid increase in the flow of lymph from the opened duct, and that the lymph became less coagulable. While ordinarily the giving of fluids by mouth in peritonitis will increase the absorption, when lymphaticostomy has been done it is safe to give them, thus ensuring a steady flow of lymph and a washing away of the toxins.

I have had the opportunity of performing the operation in only one case since that reported in March, 1923.[1]

The operation was done on April 21st, 1924, on a boy aged 10 years, who was referred to me by Dr. A. J. Williusky of Toronto. He had opened the abdomen after the boy had been ill four days, and found a ruptured appendix and diffuse peritonitis. He removed the appendix and drained the abdomen and the ileum close to the caecum. When I saw the boy, a day later, he was clearly going downhill. Gas and oxygen were given and the duct drained. The flow was profuse for forty-eight hours, lessened on the third day, and had ceased by the fifth. The flow of lymph *on opening the duct obscured a view of the opening*, so that I had to use a piece of silkworm gut which was passed about an inch down the duct. A rubber tube was then threaded over the silkworm gut down to the duct and wrapped round with a little plain gauze. Mackenzie's silver cannula, which he describes in the BRITISH MEDICAL JOURNAL of June 21st, 1924 (p. 1114), might well be used, provided the lymph was not too highly coagulable. The tube and silkworm gut were removed on the second day and the gauze on the third. The boy made a good recovery, and his family physician states that he is now in good health.

Five cases have been recorded in the literature, of which four were successful. All the cases were apparently hopeless. Edwards[2] operated successfully under local anaesthesia in a woman suffering from puerperal peritonitis. Cooke[3] reported the first case of peritonitis secondary to appendicitis which was successful. The case of "ruptured intestine" reported by Mitchell[4] was unsuccessful.

The difficulty of finding the duct in the cadaver is due to the fact that the duct is collapsed and in that condition resembles fibrous tissue. It is more difficult to find in the dog than in man.

The indications for the operation are not yet clear. It is not an easy matter to say when the patient is experiencing a continual septic absorption which is going to prove fatal, and surgeons are not unanimous in accepting the theory that most of the post-operative symptoms considered to be complications are due to that absorption. Septic absorption in peritonitis leads to increasing distension, obstipation, vomiting, and that peculiar combination of subnormal temperature, rapid pulse and respirations, and mental acuteness which renders the patient aware of the impending end.

In secondary peritonitis such as the case which Coole described, the operation is definitely indicated as an adjunct to dealing with the condition locally. It may be necessary in certain cases to submit the patient to the two procedures simultaneously. In all cases of secondary peritonitis when only the abdominal operation has been done in the first instance, lymphaticostomy is indicated when in the post-operative course the patient shows symptoms of a continuation of the absorption, and it is highly desirable that the operation be not delayed until the measure could not carry any hope of recovery. It is indicated in those cases of primary peritonitis, especially the pneumococcic, in which the diagnosis is clearly established. When the diagnosis is doubtful the abdomen should be opened first in order to verify the condition.

I believe that with good judgement in election and skill in the performance lymphaticostomy will lower the mortality rate in diffuse peritonitis by saving those to whom relief could not otherwise come.

W. A. COSTAIN, M.B.,
Department of Surgery, University of Toronto.

Reports of Societies.

UTERINE BACKWARD DISPLACEMENTS

A MEETING of the North of England Obstetrical and Gynaecological Society was held at Liverpool on October 17th, the President, Professor A. DONALD (Manchester) in the chair.

The PRESIDENT opened a discussion *on the treatment* of mobile backward displacements of the uterus. After referring to the significance of backward displacement, he drew attention to the difference of opinion amongst writers on the subject, and gave an account of the beginning of the passive congestion theory. Passing then to the later explanations of various modern writers, he cited the objections to the congestion theory, and emphasized the point that retroversion was not the cause of endometritis or chronic metritis. There was some difficulty in explaining the effects sometimes produced by a pessary. As a result of investigating the symptoms he concluded that *complications* were generally the only things that mattered in cases of retroversion. The complications were disordered uterine function, increased weight, prolapse, and adhesions. None of these complications were produced by retroversion. In a small proportion of cases an apparently simple retroversion caused local pelvic discomfort, and even a certain unexplained effect on the nervous system. The treatment of retroversion was nearly always *the treatment of complications*. *More than 90 per cent. of all the patients sought relief from symptoms* which were common to all cases of endometritis and chronic metritis, and for these curetting was nearly always advisable. A series of cases in which curetting had been the only treatment was recorded. Mechanical treatment included pessaries and fixation or suspension operations. Pessaries seemed to be of use as a temporary measure in cases of sterility and early pregnancy, and very occasionally in uncomplicated retroversion. There were far too many operations for fixing and suspending the uterus; the great majority were unnecessary, and many *of them were harmful*.

Professor HENRY BRIGGS considered that a student, ignorant of all gynaecology, including its nomenclature, would naturally classify the backwardly displaced uterus within the pouch of Douglas as a hernia, and would aim at strengthening the deep portion of the pelvic floor and rectifying the position of the uterus. The earlier the effort the better *the prospect of the radical cure of a hernia*. There were still gaps in the foreground of the picture of obstetrical progress. It was, for example, more than singular to have to acknowledge that the best use *of a 3-in. or 3½ in.* ring pessary in the treatment of the retroflexed gravid uterus was advocated twenty-four years ago by the late Sir William Sinclair (*Trans. Obstet. Soc.*, 1900), even to-day this advance was not to be found in obstetrical textbooks. Professor Briggs had not the least doubt that the pessary and frequent urinary catheterism in their gentle and persistent effect totally outclassed *manual reposition*.

Dr. G. W. FITZGERALD (Manchester) agreed *that all retro-displaced uteri did not require treatment, and that symptoms accompanying the displacement were not necessarily due to it. The important matter* was to determine which treatment would give the best results. If the curette could show results equal to those of abdominal section, then the minor treatment was to be preferred. He curetted all cases in which symptoms were present, and only rarely found more radical treatment necessary.

Dr. J. E. GEMMELL (Liverpool) agreed with Professor Donald that *simple retroversion* in single women was symptomless in the majority of cases. In parous women however, he thought that this displacement was in itself capable of producing a *definite train of symptoms*. He believed that there was a world of difference between an organ *that had developed* in a particular position of version and one that acquired such a position. The one was in its proper physiological place, the other had acquired a pathological displacement. The vessels of the former had been congenitally adapted to meet the requirements of the uterus in [illegible]

embarrassment to the circulation, whilst in cases of acquired retroversion the vessels shared in the displacement, and were thereby exposed to abnormal pressures that chiefly fell on the veins, and led consequently to back pressure and congestion The resulting symptoms simulated those of endometritis and metritis, but he believed they were essentially due to congestion, the result of acquired displacement He was therefore a supporter of the mechanical theory, and considered there were three clinical types which demanded correction and fixation (1) A limited number of congenital cases in which the patient complained of sterility, repeated abortions, dysmenorrhœa, or dyspareunia the type with neurosis and backache was expressly excluded (2) Obstetric types with the following cardinal signs—a bulky, tender, œdematous and often incarcerated (but not fixed) uterus, associated with pain, menorrhagia, leucorrhœa or dyspareunia (3) Cases of simple retroversion accompanied by early prolapse in young women of childbearing age This third group was not included in the tables given later Although pessaries and general therapeutic measures were useful adjuncts and might even be curative in mild cases, he limited himself to the surgical treatment of this condition, and based his remarks upon 125 cases of simple retroversion published by himself in collaboration with Mr Leyland Robinson [1] The principles of ventrifixation were not generally understood, and he believed that this procedure had acquired an unpopular reputation because most gynaecologists had studied the wrong type of operation The type he favoured was planned to fulfil the three essentials upon which the success of all gynaecological operations depended—namely (1) freedom from immediate risks, such as intestinal obstruction, (2) freedom from the risk of interfering adversely with subsequent conception and parturition, (3) ability to relieve symptoms The proof that ventrifixation met these requirements was furnished by the following facts

1 In upwards of seven hundred ventrifixation operations performed by him only one patient had died from sepsis and this one in circumstances that had nothing to do with the operative procedure The patient became unmanageable removed her dressings and escaped from the ward to the lavatory on the day after the operation There were no cases of post operative strangulation of gut

2 In 220 cases in which a complete after history was obtained 63 women subsequently became pregnant and were safely delivered of 104 children without a single case of dystocia or stillbirth occurring

3 The effect of ventrifixation on symptoms (85 6 per cent cures)

Successful operative technique depended upon three chief factors the choice of a suitable fixation point, the prevention of adventitious intraperitoneal bands and holes through which the gut might strangulate, and the achievement of a fibromuscular fixation and not of a peritoneal suspension Operations which fixed the fundus, or anchored the upper part of the uterine body, were naturally prone to accidents which demonstrated the danger of such methods These accidents had also been widely advertised to discredit the principle of ventrifixation The level of the utero vesical fold was unaffected by the changes of pregnancy, and remained passive during labour, it might therefore be described as a normally fixed point There could be no serious anatomical or physiological objection to fixing a point that was already stationary, and he therefore selected this area as his fixation point, attaching it by means of two silkworm gut sutures to the rectus fascia immediately above the symphysis pubis The prevention of adventitious bands was brought about by the construction of a bladder septum, the peritoneum covering the bladder was picked up by a series of Spencer Wells forceps from the utero-vesical reflection above to the parietal peritoneum below at the lower angle of the incision A fold was thus made across the middle of the utero-vesical pouch through which a continuous catgut stitch was passed, tied and, lastly, attached to the fascia just above the symphysis pubis This septum obliterated the supravesical space that would otherwise persist below the fixation area it formed with the new supporting ligament one continuous wedge shaped structure that effectually eliminated the possibility of loose bands or peritoneal hole It should be noted that the septum was formed of peritoneum only, and played no part in supporting the uterus The efficiency and permanence of both the septum and the new fibromuscular ligament had been repeatedly seen at long intervals after the original operation, when such patients had returned with other lesions requiring abdominal section He believed in short, that retroversion was a mechanical defect that was competent to produce symptoms, and he was convinced of the utility of the operation of ventrifixation

Mr W Gough (Leeds) agreed that many patients with retrodisplacements had no symptoms If the patient was made aware of the retrodisplacement a vicious cycle might be set up Briefly, his practice was if no symptoms were present to leave the patient alone if symptoms were present he curetted the uterus and replaced it If the displacement recurred the uterus was replaced and a Hodge pessary inserted for two to three months If the patient was thereby relieved, nothing further was done but if her symptoms returned he then operated He had tried all types of operation except absolute fixation, and found them all equally successful

Mr Robert A Hendry (Liverpool) read conclusions abstracted from the opening report on the "Indications for surgical intervention in retrodeviations of the uterus apart from pregnancy," presented to the Congress of the Association of French-speaking Gynaecologists and Obstetricians, Geneva, 1923 These were to the effect that surgical intervention in uterine deviations, apart from pregnancy, was indicated as follows

1 In retrodeviations accompanying uterine ovarian or parovarian tumours in so far as these tumours did not necessitate the sacrifice of the uterus the pexy was a complementary operation

2 In fixed and painful retrodeviations

3 In fixed retrodeviations accompanied by appendage lesions unilateral or bilateral which had resisted medical treatment If the appendage lesions required ablation it might be necessary to practise total or subtotal hysterectomy if such was not the case the uterine pexy was only a complementary operation

4 In painful mobile retrodeviations surgical intervention was only indicated if when the uterus was replaced the painful phenomena disappeared In other cases the pains are (*a*) from hysterical state etc (*b*) from multiple visceral ptoses

5 In certain rare cases of obstinate sterility where no other apparent cause could be discovered

6 In retrodeviations accompanied by repeated abortion where carcinomatous examination eliminated the possibility of syphilis

7 In all cases where in addition to the retrodeviation there was a tendency even if slight to prolapse with or without perineal lesions If the perineum was damaged the pexy ought to be preceded by careful vagino perineal repair

8 Painless mobile retrodeviations did not require any treatment

The discussion was adjourned until the next meeting which will be held at Sheffield on November 21st

Prior to this discussion Professor Blair Bell (Liverpool) described a case of manual perforation of the puerperal uterus Abdominal pain followed a normal confinement on the third day of the puerperium the temperature rose to 103° F, intrauterine douches were employed Fourteen days after the confinement the uterus was explored and a large quantity of tissue—subsequently found to be uterine muscle—was removed manually Suddenly the operator found his fingers pass through the uterine wall Three hours later panhysterectomy was performed with removal of a left sided, twisted, ovarian cyst, which was in front of, and was mistaken for, the fundus of the uterus The patient made an excellent recovery

Professor Henry Briggs (Liverpool) remarked on the escape from gross infection during and after the labour The occurrence of embarrassment arising from lack of acquaintance with the interior of the full term uterus after a complete labour pointed to the necessity for more practical work in museums and classroom

Dr J H Willett (Liverpool) commented on the difficulty of removing the placenta in certain cases and referred to a specimen in the University obstetrical museum in which the placenta could not even be separated in the laboratory after the uterus had been removed

Professor A Donald (Liverpool) emphasized the facility with which the uterus could be perforated during the puerperium, especially if infected

Professor Blair Bell also described a case of thrombophlebitis of the right ovarian vein associated with abscess in the uterine wall The confinement was normal Nine

[1] *Lancet* June 18th 1921.

days later the temperature rose, the uterus was curetted and washed out with iodine, and a rigor followed The temperature subsequently ranged between 103° F and 105° F The patient was removed to hospital a fortnight after the delivery *Streptococcus longus* was recovered from the uterus, which was washed out three-hourly with 1 in 20 hypochlorite solution without any definite improvement A fortnight later panhysterectomy with removal of both appendages and thrombosed ovarian veins was performed A portion of the ovary was used as a graft The temperature subsided, and the patient made a good recovery

Professor Henry Briggs deduced that the bacterial infection in this case was of a mild character and that the lymphatic inflammation was localized

Mrs Dobbin Crawford (Liverpool) reported a case of primary carcinoma of the vagina in a patient, aged 68, who complained of backache and dysuria, on one occasion, three weeks before, a blood stain was found on the sheet Her previous health was good, her husband had died two years previously of gastric cancer In the upper part of the vaginal wall, in front and to the left, were several flat bluish-purple bosses, fixed to the underlying tissues but not ulcerated, the cervix was normal and was not encroached upon by the tumour Cystoscopy showed a dusky area in the base of the bladder The growth was curetted and cauterized with zinc chloride On section the growth proved to be a squamous-celled carcinoma A vesico-vaginal fistula occurred eventually, the patient survived the operation only four months

SPONTANEOUS UTERINE RUPTURE

The Plymouth Medical Society held a clinical meeting on October 21st, with the President (Mr C Ll Linder) in the chair

Mr James Riddell showed a specimen of spontaneous rupture of the uterus during pregnancy at about seven months The predisposing causes were described as (*a*) curettage and douching of the uterus, (*b*) manual removal of the placenta, (*c*) syphilis, and the exciting cause as sexual intercourse and indirect traumatism The site of the rupture was on the anterior wall near the fundus, it was transversely placed over the placental site and was one inch in length The diagnosis made was ruptured extrauterine pregnancy with internal haemorrhage, the treatment included laparotomy and subtotal hysterectomy The patient recovered Dr Eric Wordley said that the uterus in this case was devoid of muscular tissue at the fundus Sections of muscular tissue from other parts of the uterus showed hyaline degeneration, cloudy swelling, thickened and thrombosed vessels, and diffuse fibrosis throughout The degeneration was of long standing No spirochaetes were seen

Dr Twining showed a man, aged 79, with symmetrical tumours on the inner sides of both thighs which were believed to be fibromata or, in view of the rapidity of growth—nine months—fibrosarcomata Operative treatment was deemed inadvisable for reasons of age Mr H G Pinker showed a specimen of carcinoma of the splenic flexure of the colon which had produced a chronic intussusception in a man aged 53 After removal of the growth and intussusception the transverse colon was anastomosed to the pelvic portion, and the patient made a good recovery

Dr Thomas showed a specimen of sarcoma of the kidney removed from a child aged 4½ The growth was extremely rapid, only a small portion of healthy kidney substance remained Mr Hamilton Whiteford showed a breast removed on account of carcinoma, and emphasized the importance of (1) radiography of the thorax to exclude secondary deposits in the lungs, (2) incision into the growth itself before carrying out a radical operation He exhibited the radiogram of the chest in his case, in which there were shadows of doubtful significance, he had considered it advisable in all the circumstances to carry out a radical operation

Reviews.

BLACKWATER FEVER IN SOUTHERN RHODESIA

The London School of Hygiene and Tropical Medicine has just published a record and report of investigations carried out by the Director of its Protozoological Department, Dr J Gordon Thomson, into blackwater fever during 1922 and 1923 in Southern Rhodesia, where he went in charge of a Research Commission to study the subject[1] Funds for the undertaking were supplied by the Rhodesian Government, the disease being one of serious moment in that territory The publication sets out how much has been achieved, and, as in other cases, so now again it is shown that money devoted to the cause of public health is not lost, but is, on the contrary, a lucrative investment The Rhodesian authorities will be able to realize that their money was wisely entrusted, and to congratulate themselves on their public spirit, since this work in their country will be of benefit to all tropical countries where malaria and blackwater fever are found Those who were present at the meeting of the Tropical Section of the Royal Society of Medicine when Dr Thomson discussed the relations between malaria and blackwater fever will welcome this fuller account of what was put before them briefly on that occasion

After a short introductory chapter Dr Thomson describes the topography of Southern Rhodesia and the geographical distribution of blackwater fever throughout the world giving a concise history of the disease Next follows an interesting summary of its relationship with malaria, a subject further developed in the succeeding chapter, when the association of the malignant tertian parasite with blackwater fever is discussed The author shows that the older asexual forms, by bringing about the malignant stippling, or Maurer's dots, lead to the production of the "brassy corpuscles", these, he believes, then become, as it were, foreign bodies, which provoke the formation of a specific haemolytic amboceptor This haemolysin in the presence of complement acts on corpuscles so altered, but not on normal corpuscles, nor on those harbouring young parasites Consequently, these last persist throughout the paroxysm, and the fact that they may be very few in number accounts for the discrepant statements of different authors, some maintaining that malarial parasites persist throughout the attack, others denying their presence The hypothetical *Spirochaeta* or *Leptospira haemoglobinuriae* disappears, for "pseudo-spirochaetes" indistinguishable from those described have been obtained by the author in blood from normal individuals, and he has shown that they originate from blood platelets and damaged corpuscle Moreover, inoculation experiments with them gave negative results invariably

Haemolysis in general is discussed, and the various agents which may bring it about It is shown also that the mode of its production in blackwater fever differs essentially from that in other conditions The chapter on pathology is comprehensive and deals with the blood plasma, the red corpuscles, the leucocytes, various tissues, and organs Special sections are devoted to jaundice and its mode of production in this disease, and also to the urinary changes The clinical aspect is treated very briefly, within three pages, but since this subject receives such detailed consideration in textbooks, anything more would be mere repetition The chapter on treatment and prophylaxis is most instructive, the questions of the employment of quinine and of the method of its administration when used are ably discussed and cases are described showing that in some patients an attack of blackwater is precipitated by this drug It is shown, however, that quinine in the blood stream probably plays no direct part in the haemolysis of blackwater fever, but that its action must be indirect and in association with some other factor Other forms of treatment, such as Sternberg's mixture, Hyem's serum,

[1] *Researches on Blackwater Fever in Southern Rhodesia* By Gordon Thomson MA MB ChB London School of Tropical Medicine Research Memoir Series No VI London 1924 (7 × 9 in viii+149 pp 10 plates 12 charts 5s)

Calmette's antivenine, and auto-haemotherapy, also receive mention

The publication contains some good reproductions of photographs showing "blackwater fever houses", there are also two excellent coloured plates depicting various forms of corpuscles and the parasites, in which the close resemblance to Babesia is clearly brought out The photomicrographs of tissue sections are on the whole good, but such a process does not lend itself to the satisfactory reproduction of the prussian blue reaction, for example There is an exceptionally good bibliography, but no index

One of the charms of the work is that the author states fairly the findings and pronouncements of others, and, while defining clearly the results of his own work, he makes no claim to have solved this great problem Since he mentions the views of others, a somewhat more detailed discussion of them would have been welcome, but perhaps that would hardly come within the scope of the present record The impression derived from this report is that the foundation has now been laid for a solid structure of knowledge Much has been accomplished, but much more remains to be done

PHYSIOLOGY IN THERAPEUTICS

Since its first appearance in 1903 Dr W Langdon Brown's *Physiological Principles in Treatment* has established its position as a readable and practical exposition of the current views of physiology and pathology and their application to practice The fifth edition contains nearly a hundred pages more than its predecessor in 1919 (reviewed in our columns early in 1920) as the result of the addition of new chapters on the work of the liver and on the problems of asthma, and fresh sections on fractional test *meals, insulin, uraemia, and dyspnoea* Dr Langdon Brown points out that the earlier and simpler tests for hepatic function failed because the reserve power of the organ was not realized, so that the tests were positive only when the destruction of the liver was so advanced as to render cure impossible, and, further, that its various functions are not equally affected by disease and so individual tests are necessary The laevulose test, however, as estimated by the blood sugar, is regarded as one of the best methods of estimating hepatic efficiency The section on jaundice is largely based on the recent work of Dr J W McNee, and in it the van den Bergh test is clearly explained In dealing with asthma Dr A F Hurst's definition is accepted, and without adopting Eppinger and Hess's theories in their entirety, the asthmatic patient is regarded as a vagotonic and liable to other manifestations of vagotonia In both these new chapters the general plan of lucidly correlating the lines of treatment with the most recent knowledge is followed With regard to Voronoff's grafting operations Dr Langdon Brown, who has seen some promising results, preserves an open mind The rapidly changing history of the treatment of diabetes in recent years is briefly sketched, and this outline gains in interest because the author has had ample opportunity of watching his colleague Dr George Graham's scheme of the "ladder diet" This diet is compared with Allen's, and the view is expressed that it is perhaps less rapid in removing glycosuria, but less likely to injure the general health of the patient The uses and indications for insulin are carefully indicated While not overladen with references, the work of others is freely mentioned This edition fully maintains the well established claim to popularity of a pleasantly written and useful work

CYTOLOGY

General Cytology,[3] described as a textbook of cellular structure and function for students of biology and medicine, is a collection of monographs on the fundamental structure and functions of the cell It has been written by research workers connected with the Marine Biological Laboratory at Wood Hole, Massachusetts, and no less than thirteen authors, all of them being recognized authorities in their respective fields, have contributed chapters

They have produced an imposing volume of 754 pages with hundreds of illustrations, and with bibliographies containing thousands of references The functions and structures of the cell have been studied from every angle, and the result is a comprehensive and authoritative summary of present knowledge concerning the laws governing the ultimate units of living protoplasm

The most original and striking contribution is that by Professor A P Matthews, who has had the courage to tackle anew, in an essay of eighty pages the age-old problem of the nature of life With the aid of relativity the quantum theory and the recent advances in our conception of the ultimate structure of atoms and molecules, he finally arrives at the following conclusion

> The great difference between the living and dead is a difference in the energy content of the molecules and atoms in the two states All substances electrons atoms and molecules can and do exist in two forms energy rich and energy poor form I have proposed to call the former the anakinetomere and the latter the katakinetomere The former is the living the latter is the dead form The creation of life is the creation of the anakinetomere form

This seems to be little more than a restatement of the problem with the introduction of two new terms, and does not help very much The other monographs proceed along more usual lines of thought, and deal with more concrete and prosaic problems Professor M H Jacobs gives a brilliant summary of knowledge regarding the permeability of the cell, his article is of particular value as it incorporates a large amount of recent American work which is of fundamental importance for the consideration of this difficult problem Dr P S Lillie deals with the reactivity of the cell and discusses the general nature of the response of protoplasm The consideration of the problem involves discussion of the nature of the electrical and chemical changes occurring as a response to stimulation and the manner in which the response is modified by changes in temperature, by anaesthetics and other agencies The author also gives a summary of his own interesting views as to the nature of protoplasmic transmission He considers that the process consists of a wave of surface change passing along the cells, and indicates interesting analogies between the transmission of excitation in protoplasm and the waves of surface change that occur when iron made passive by treatment with strong nitric acid is dipped into weak acid

The article on fertilization, by F P Lillie and E E Just, gives an account of the physiology of the process, and describes the various chemical treatment by which fertilization can be induced or inhibited a subject with which American workers are particularly associated

The majority of the remaining articles are devoted chiefly to the microscopic structure of cells and this is dealt with from various aspect The book concludes with two chapters on the chromosome theory of Mendelian inheritance and an account is given of the experimental work done chiefly on the fly drosophila, which has led not merely to assigning specific characters to each chromosome, but even to the production of schemes showing the exact way in which the genetic characters are arranged or packed in each chromosome—an achievement which impresses the imagination as much as the physicists' efforts in tracing the movements and habits of individual atoms

This summary shows how wide is the range covered by the articles in a book which should appeal to a large circle of readers, cytologists physiologists and pathologists Each will find that the article on the subject he knows best is comprehensive and considered summary of the latest knowledge and that the articles on less familiar subjects are clearly written and easy to follow The book thus gives the reader the opportunity not only of acquiring recent information and useful references in those branches of cytology with which he is best acquainted but also of obtaining a reliable summary of the state of modern knowledge in less familiar fields

INDIAN STORIES

Some forty years ago the late Mr C H Tawney prepared a translation of the Sanskrit *Ocean of Story*, but unfortunately, as the very apt publisher's circular issued with Mr Penzer's edition explains, it was issued in Bengal and was never reprinted, and hence this wonderful collection of Oriental tales is little known

In the first instance we owe this collection of stories to Somadeva, a Brahman who lived in the eleventh century A D But, albeit they are overlaid with a strong Brahmanic tinge, they are certainly not all Aryan in origin, and it is the opinion of Sir Richard Temple, expressed in his foreword, that they go back to a much older period, having been taken by the editor from the popular Indian folklore of his day This, as he says, opens up a series of problems for discussion, the first being whence this non-Aryan element came?

"The Aryan invasions of India were spread over a long period and the progress about the country was very slow The Aryans came across at least one race, the Dravidians, equal to themselves in mental capacity The consequent development was on the recognized lines of evolution it was fundamentally Aryan, with accretions from every race with which the Aryans had come in close contact"

This is the problem on which Mr Penzer's voluminous notes and discussions are intended to throw light He has had nothing to do with the translation, which is practically Mr Tawney's original text, supplemented in a few details by Dr L D Barnett, his has been the labour obviously of love, to try to trace the migrations and origin of these stories with their wealth of folklore containing so many finger-posts to their connexions with the past We are a long way yet from the earliest *jongleurs* of history, but a book such as this is a fresh foothold across the difficult morass of antiquity Probably the most important note in the book is Mr Penzer's discussion of sacred prostitution—a most difficult problem In the *Ocean* a lady named Rupinika is a courtesan who at the time of worship went into the temple to perform her duty, and it is to this quotation that the consideration of the question is appended Briefly, Mr Penzer's opinion is that it is difficult to say to what extent the custom existed in ancient India, although it seems clear that from the Buddhist age onwards the prostitute was held in some esteem, in fact "in Vedic times reliable evidence is insufficient to enable us to form any definite conclusion as to the possibility of distinct connexion between religion and prostitution", even is late as the early Christian era ("we still find no direct reference to the *dêva-dâsi*" (hand-maid of the gods) About the twelfth century, however, the evidence becomes more definite and geographical, and it appears that the further south in India the inquiry is pushed the more is the custom found to be recognized Mr Penzer then correctly makes full comparison with the ancient Babylonian customs similar to this, there is no doubt that at Erech, the seat of the worship of the mother-goddess Ishtar, religious prostitution was definitely recognized, and had been so from time immemorial Other nations in the Near East maintained the custom too indeed, Mr Penzer goes further afield into West Africa for his material It is one of those lines of comparison which throw light equally on the old temple rituals and the migrations not only of people but of traditions

We have no space to go into the other discussions—the shoes baked in queer shapes, the magical shoes which, like the seven-leagued boots transport the wearer out of danger, the legend of the bitch and the pepper We could suggest another parallel (that of the Babylonian Etana borne up by the eagle) which might have been included in the note on the mythical Garuda bird But the reader will have seen from what has here been said that great interest attaches to this book, and, if he have an leanings towards Eastern folklore, we can heartily recommend it to him The translation of such a wealth of stories offers to the student particularly those who are not Sanskrit scholars, a mine of quee parallels to the legends in their several spheres, and Mr Penzer's illuminating notes are full of pregnant suggestion A most admirable index completes the first volume

R Campbell Thompson

GUY'S HOSPITAL REPORTS

Of the nine papers in the third quarterly instalment of this year's volume of the *Guy's Hospital Reports*,[1] the first three deal with the biliary tract and three others with the stomach In their investigation of the duodenal contents and bile in man, Drs J F Venables and F A Knott of the New Lodge Clinic review 100 consecutive examinations of the duodenal and gall bladder contents, in no instance was it possible to recognize the three types of bile—from the common bile duct the gall bladder, and the liver —described by Lyon of Philadelphia, and, contrary to Rosenow, the infecting organism in cholecystitis was almost invariably *B coli* and never streptococci From a careful microscopical examination of ten recently removed gall bladders Drs Knott and Bowell discuss the formation of gall stones, and conclude that neither the infective theory put forward by Yamyn nor Aschoff and Bacmeister's bio chemical hypothesis will alone prove to be satisfactory, but that both factors must at one time or another act in a complementary manner They describe as the initial stage of a gall stone an intramural deposit of cholesterin in con junction with damaged or necrotic epithelium Mr W L Tanner's analysis of 117 operation cases of cholelithiasis shows that removal is preferable to drainage of the gall bladder In a successfully illustrated paper on the diagnosis of gastric and duodenal ulcers by x rays, Drs A F Hurst and P J Briggs describe both the indirect evidence, to which comparatively little has been added since 1914, and the direct evidence—namely, the deformity pro-duced by the ulcer in the outline of the stomach or duodenum—which has become much more available as the result of the improved technique during the last five years In fact, every chronic peptic ulcer, however small, can now be recognized by the direct evidence, though a small congenital diverticulum close to the cardia may closely resemble the "crater" of a large gastric ulcer Drs J M H Campbell contributes two interesting papers—the first with Mr M Burd and Mr J R Hein, the second with Dr J J Conyberre—on the correlation of physical fitness and physique with gastric conditions, so as to throw light on the existence of an underlying diathesis favouring the occurrence of peptic ulcer The examinations conducted on healthy students at Guy's Hospital confirmed the view that certain anatomical and physiological variations present in health may be the physical basis of the subject's diathesis to develop gastric disorders under appropriate conditions In describing the insulin treatment of diabetes, Dr W W Parne, working under Dr E P Poulton, records a large number of observations, including some to test the effect of combining parathyroid treatment with insulin, some of the few cases thus tested showed evidence that the parathyroid therapy might diminish the blood sugar Drs R D Passy and J Cuter Brune find that in the intestinal sprue and of *Dibothriocephalus latus* infection the red blood corpuscles show the same increase in size and in the distribution curves as in Addison's anaemia Mr G E Gibbard[2] note on two cases of neurofibroma of the cervical sympathetic is the last in this interesting instalment

NOTES ON BOOKS

The new edition of the small handbook on the diagnosis of internal diseases[3] by the late Dr Georg Klemperer, who died shortly after completion of the manuscript in November, 1922, has appeared within three years of the last edition (see JOURNAL November 5th, 1921, p 751) The work has undergone general revision and has been well brought up to date, special attention having been paid to roentgeno copi

[1] *Guy's Hospital Reports* Vol lxxiv (3rd fourth series) No 3 Jul 1924 Edited by Arthur F Hurst M D London Wakley and Son (1 Ld 10s 6d (Med 8vo pp 245-368 63 figures 12s 6d each) volume of four parts single numbers 12s 6d each)

[2] "Differential diagnosis of the nerves and their tumours" Part Dr C Ellis mann Eighth and ninth edition Leipsic J A Barth 1924 (Med 8vo pp viii + 253)

[3] *The Ocean of Story* Being C H Tawney's translation of Somadeva's Kathâ Sarit Sâgara Now edited with introduction footnotes and illustrative matter by N M Penzer M A F R G S F G S With foreword by Sir Richard Carnac Temple In ten volumes Vol I Privately printed for subscription only by C J Sawyer, Ltd London 1924 (Demy 8vo pp xii + 350 12 2s per volume)

The *Collana Medica "Murri"* is a series of eight medical booklets which have been published by L Cappelli of Bologna apparently with the object of popularizing the treatment of the more common complaints such as neurasthenia and nerve troubles, syphilis, constipation defects of vision, infantile diseases, insomnia, and tuberculosis The volumes on infantile diseases, insomnia, and tuberculosis[7] have been the last to appear They give a clear description of the causes of the complaints with which they deal and their treatment They are evidently intended to enable the patient, or those on whom in home life he is dependent, to help in the treatment by individual effort and by an appreciation of the causes and rational treatment of the complaints, and not for the purpose of eliminating the medical attendant The booklet on insomnia for example, concludes with a sentence to the effect that, after all, and especially in insomnia of nervous origin the wise course is to consult a physician in whom one has confidence, to whom one may unburden one's mind, and from whom one will get good advice This is the kind of advice popular books on medical subjects should give the reader

Dr W STEKEL of Vienna seems to be one of the most voluminous of living writers It would appear that a number of his books are to be translated into English, and the first of these has been issued under the title *Conditions of Nervous Anxiety*[8] Dr Stekel considers that in the progress in chemistry, physics, bacteriology, and pathology we have neglected the psychic components of disease, and his book is intended to serve as an introduction to psychotherapy for practitioners He claims the credit of having built up the real psychology of neurotic anxiety by the amplification of Freud's teaching and by modification of some of his errors Formerly he thought with Freud that all anxiety was of sexual origin, but during the war he became convinced that the instinct of self preservation can produce an elety without any sexual constituent owing to the conflict arising between the instinct of self preservation and the sense of duty The greater part of the book, however is taken up with the detailed description of cases illustrating the occurrence of anxiety conditions as the result of repression and violation of the sex instinct There are chapters also on anxiety neurosis in children and the technique of psychotherapy The translator, on the whole, has done her work well although her lack of familiarity with medical terminology is a drawback

The cult of beauty in woman (and man) is ancient, it is modern and is not likely to diminish in the future The standard of human beauty has varied and varies to-day but it has never failed to attract and be desired and there have been many attempts to cultivate it M MASQUILIER[9] in his book bursts into rhapsody on the practice of 'morphotherapy,' or the education of the beauty of the human body He conceives of beauty of form of movement, and of expression, and tells how they have been sought after in systems old and new For him the modern town dweller waxes old before he is young he is like a slow combustion stove that has become clogged and needs the forced draught of physical cultivation All women—he must mean all who don't work or take to sports—are atrophic hiding wasted muscles under an adipose coating Yet even he can see some improvement since they have discarded the corset and freed the neck bosom and lower limbs from the thraldom of clothes The cult that he urges is summed up in the word "re education —the discovery of the undeveloped or wasted function and the recovery of it Movements—active and passive, free and controlled—massage the reform of diet ary and of the mode of life, all are made servants to the idea of re education and in that there is beauty for all It is an essay not without truth, and not without interest, albeit the adjectives are too often in the superlative

DRS IRVING J SANDS and PHYLLIS BLANCHARD have conjointly written a book on *Abnormal Behaviour*[10] which serves to demonstrate the change which is taking place in the attitude of the community towards the individual who does not conform to its customs and standards of conduct Formerly, as the authors point out the person who showed aberrant behaviour traits was looked upon as a social outcast whereas now the tendency is to look upon such an individual as mentally ill and to seek for the cause of his abnormal conduct The book deals largely with concrete cases of the various forms of abnormality full descriptions are given, the causes discussed and the mode of dealing with them indicated The treatment of the subject is elementary and the book is thoroughly suited to the needs of the social worker

PREPARATIONS AND APPLIANCES

Oxo id Glandular Preparations

We have received samples of a series of Oxoid glandular preparations recently placed on the market by Messrs Oxo Ltd The following are the chief preparations

Thyroid gland tablets gr 5 2 1 1/2.

Pituitary gland
- Anterior lobe tablets gr 5
- Posterior lobe tablets gr 2
- Whole gland tablets gr 5
- Liquor hypophysis 20 per cent and 10 per cent extracts

Suprarenal body
- Suprarenal gland tablets gr 5
- Adrenaline tablets gr 1/60 and 1/120
- Adrenaline solution 1 per 1000

The makers claim that the fresh glands are desiccated by methods devised to give the maximum preservation to the active principle that all subsequent chemical processes are conducted with extreme care and that the final products are standardized to a uniform strength by modern chemical and biological tests.

Tests made for the BRITISH MEDICAL JOURNAL upon the adrenalin and posterior lobe pituitary preparations showed that they had a high physiological activity

It is interesting to note that Messrs Oxo are applying their thyroid preparations to pharmacological and therapeutic tests This is a very satisfactory departure for it gives the medical practitioner receiving thyroid preparations of uniform activity This of course is not ensured by the ordinary chemical tests The prices charged for the preparations are moderate and reasonable

A Packing for Surgical Dressings

Under the name Steradis Messrs Robert Bailey and Son of Marriott Street Mills Stockport have devised a simple method of packing for urgical dressings It consists of a double cylinder of cardboard the inner cylinder containing 3 or 6 yards of plain or medicated absorbent gauze Each cylinder is slotted or perforated its full length By rotating a flange at the bottom of the inner cylinder the edge of the gauze appears in the slot of the outer cylinder When the two slots are opposite one another the amount of gauze required can be drawn out and cut off the apparatus is closed by turning the flange in the opposite direction The principle is simple and effective and prevents the exposure of the dressings to the atmosphere or to handling It should prove a very handy method of keeping dressings in the surgery and for first aid purposes.

ROYAL MEDICAL BENEVOLENT FUND

At the last meeting of the Committee fifty seven cases were considered and £673 0s 9d voted to forty-seven applicants The following is a summary of some of the new cases relieved

Widow of M D Edin who died from influenza a few days after the birth of her fifth child two days after Applicant is left with three young children aged 11 5 and 2 Her total income is £1 5 She asks the Fund to help with clothes for the second boy A small grant was made and the case handed over to the Guild.

Daughter aged 20 of L R C P and S Edin who died of heart disease in an artist and was employed by a firm of firework makers at Her income her out of employment Her rent is 14s 6d per week From January to April he managed to make £4 a week but since then has only been paid £2 0

Widow aged 61 of L R C P Edin who died in 1922 after a long illness received £40 for the good will of the practice and also a private annuity of £50 a year from his wife's brother and has only £1 a week to live on

Daughter aged 19 of M R C S Eng who died in 1922 after a long illness and left his family in poor circumstances Applicant suffers from chronic catarrh and has recently undergone an operation for adenoids She is only able to help support by means of her income pupil and has a total income of £5

Daughter aged 9 of M R C S Eng who died in 1922 after a long illness Applicant is living with her mother and brother in a furnished house which they are about to leave as they cannot afford to keep the furniture Would be glad to have a small grant of £5

Subscriptions may be sent to the Honorary Treasurer Sir Charters Symonds K B E C B Messrs Hill Cranch Street Cavendish Square London W 1

The Royal Medical Benevolent Fund Guild has received many applications for clothing consisting of overcoats and shirts for ladies and girls holding ecclesiastical posts and suits for working boys The Guild appeals for second hand clothes and household articles The gifts could be sent to the Secretary of the Guild, 58, Great Marlborough Street, W 1

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

(*Continued from page 820*)

The sittings of the Royal Commission on Lunacy and Mental Disorder were resumed on November 4th, under the chairmanship of the Right Hon H P Macmillan, K C

Evidence of Medical Superintendent of Poor Law Infirmaries

Dr A L Baly, medical superintendent of Lambeth Infirmary, was the first witness He said that the accommodation for mental cases in his institution consisted of four wards with 50 beds for women, and one ward with 11 beds for men, he hoped to increase the accommodation on the male side within the next few months The cases which came under observation ranged through every degree of mental disorder A magistrate attended two days a week for the purpose of certification During the year ending March 31st last the number of persons brought before this magistrate was 615, the majority (453) were admitted on the request of the relieving officer of the police under Section 20 of the Lunacy Act, which provided for three days' detention, other cases were transferred to the mental department from the general wards of his own or another institution Of the 453 cases on three days detention, 193 were afterwards transferred to mental hospitals, in 111 other cases the orders were allowed to lapse, and the remaining 149 were either eventually discharged or transferred to the general wards Very many of these cases were technically short of lunacy, and yet it was advantageous to the patient to be for a time under control The cases transferred to mental hospitals were those amenable to treatment, for which there was no provision in the Poor Law infirmary, cases returned in the infirmary were chronic, and mostly senile The constant difficulty with which he was faced was not in saying whether a person was of unsound mind but whether it was proper to place him in a mental hospital, the answer to this second question depended largely on the patient's home conditions A scheme whereby persons of unsound mind might be placed on trial without certification would remove a great deal of the difficulty The friends of the patient were almost invariably anxious that he should not be certified, and many of the cases of mental unsoundness which found then way to a Poor Law infirmary were obviously of a temporary nature Domestic troubles accounted for not a few of them, and he had actually had cases in which husband and wife alternately sent one another to the receiving institution Unemployment was a fertile cause of mental instability Cases which proved after observation to be clearly not certifiable were mentioned to the magistrate on his visit and discharged at once, unless the patients happened to be suffering from physical ailments, in which case they were sent to the general wards In certain cases in which it was not clear that discharge should be given, and which it was desirable to keep under observation for a longer time, he had certified but suspended the certificate, so that the patient was not sent immediately to a mental hospital and if he recovered neither he nor anyone else was aware of the fact of certification

The witness was examined at some length on this expedient, and Earl Russell pointed out that although no harm might be done, the person so dealt with could not bring in action for slander against someone who asserted that he had been certified Asked as to his own position should an aggrieved patient take action, the witness expressed the view that any medical practitioner giving a certificate of any kind ought to be protected in the same way as a witness giving evidence on oath He had taken legal advice on his own liability and had received some reassurance Asked from whom the advice had been taken, he said that it was from a Commissioner of the Board of Control, at which there was some laughter among the members of the public present The witness added that the apprehension of legal troubles was now very acute among private practitioners, who were showing a disinclination to participate in the administration of lunacy law

Asked with regard to the position of the relatives of a patient Dr Baly said that in every case an effort was made by the relieving officer, and if necessary by the police to trace the relatives The charge ability for the patient was the motive in so doing but as a medical officer he wanted the assistance of the relatives for another reason—namely, that he might learn the history of the case and then wishe with regard to the patient

Some discussion arose on the cases of patients suffering from delirium or other mental symptoms accompanying fevers, and the witness said that in his experience these cases occasionally came within the operation of lunacy administration Such cases as uræmia were sometimes transferred, for greater convenience in administration, from the general wards in another institution to the mental wards in his own, and the Lunacy Act had to be invoked to secure the transfer Only a small percentage of such people were eventually certified, and it appeared to be due to a physical condition he always did his utmost to retain the patient instead of letting him go to a mental hospital With regard to alcoholic cases, it appeared to be a matter of chance whether a person whose mental condition was due to alcoholic excess was taken to the police station or the lunacy ward

In reply to other questions, Dr Baly put forward an objection to the hard and fast segregation of mental cases He thought there were advantages in treating mental cases in a general institution, not only because the stigma was thereby removed, but because the patient had the advantage of superior vision and treatment by a general medical staff He thought that it would be sufficient to have, in addition to the staff of a general hospital, a special mental consultant The Chairman said that the Commission would certainly desire to diminish the distinction between mental and other illnesses, but the fact could not be overlooked that mental disease had the peculiar feature of disturbing the responsibility of the citizen More over, the stay of a patient in a general hospital was usually short, but mental disease, unhappily, ran a long course, and was often permanent The symptoms in many cases were also such as to make it undesirable to associate persons suffering from mental disorder with rational patients The witness replied that this was not necessarily the case He maintained that a very large class of mental cases could be treated in a general ward, for others a separate ward would be necessary, and for incurable cases there had better be a separate block or not a separate institution In reply to Sir Humphry Rolleston, he agreed that it would be an advantage for assistant medical officers in Poor Law institutions to be seconded for a short period to mental hospitals, if Poor Law institutions obtained power to retain curable patients for a longer period than was at present allowed it would certainly be necessary to have on the staff medical officers who were expert in the treatment of mental disorder A member of the public desired that some questions should be put to the witness with regard to the provision in the medical curriculum for the study of mental cases, but the Chairman said that this information would be forthcoming from a representative of the General Medical Council whom it was intended to call

Dr J Dundeon Giles, medical superintendent, Salford Union Infirmary, said that he had one male ward with 70 beds for mental cases, and two female wards with a total of 100 beds Among about 900 patients in his infirmary he had an average of 150 mental cases About 80 per cent of these patients were brought to the institution by a relieving officer or the police, and kept on a three days' detention order A very small proportion of these were discharged within the three days, and the remainder were placed on the fourteen day order for observation, Section 24 of the Act being invoked to admit of the fourteen day detention A certain number were then found to be certifiable and were removed to the mental hospital, others—chronic cases—were placed under a permanent detention order It one order lapsed without a definite step being taken the patient was discharged altogether to another ward and "tried out" for a day or two, and if the symptoms still remained the matter was taken up *de novo* He felt strongly that a period of observation and provisional treatment, with some sort of control, should be allowed by law before certification But it was very necessary to have some power to say to relatives that a particular patient during a certain period must not be taken out of the institution Provision for treatment without certification would certainly encourage people to come forward voluntarily at an early stage of then malady He thought that the fourteen days detention period might usefully be extended to a month He agreed with the Chairman, as the previous witness had done, that the programme of action as set out in the Lunacy Acts was not at all well defined, the system, interpreted as it had been by intelligent and sympathetic medical officers, had not worked badly, but it was very desirable to have some simplification

---

An International Catholic Missionary Exhibition will be opened in Rome on December 25th, and will remain open during next year The medical section of this exhibition is being organized by several professors, and special attention is being paid to tropical diseases Educational exhibits are being collected from various countries, including England

We have received a copy of *Revista dos Cursos*, 1924, Anno V, N 10, the official organ of the Faculty of Medicine of Porto Alegre, Brazil The issue contains an introductory address by Professor Fabio Barros, occupant of the chair of physiology, followed by seventeen clinical lectures on various medical and surgical subjects, which are illustrated by numerous photographs and skiagrams

British Medical Journal.

PARLIAMENT AND MEDICINE

To DAY we give a brief account (at page 872) of the election fortunes, or misfortunes, of all the members of the medical profession who have been candidates for Parliament with the single exception of the Scottish Universities constituency, in which the polling has not yet closed Five who were in the House of Commons recently dissolved have been re elected, and there are six new members, two of whom however, had been in a previous Parliament Four who sat in the last Parliament have been rejected this time and thirteen others have also been unsuccessful, some of them having formerly been candidates or members, the unsuccessful include three medical women All parties are represented amongst the defeated but Labour predominates to the extent of ten of the seventeen The eleven so far elected consist of six Conservatives, four Labour members, and one Independent, the setback of the Liberals leaving that party without a medical member in the House

It is important that, apart from political colour, the voice of medicine should be heard in Parliament when questions involving professional knowledge and experience are under discussion, and the group as now elected contains all the necessary qualifications For the most part they have not been appointed as doctors but as belonging to one or other of the two main political parties and, as it happens the general composition of the new House of Commons is not unfairly reflected in the fact that six are Conservatives, one is Independent and four are Labour members On university education, the Health Insurance Acts the fostering of research and the regulation of animal experiments the promotion of vaccination, the welfare movements in respect of mothers infants and school children, the control of tuberculosis, the extension of institutional accommodation as preferable to home treatment for many diseases—on all these and other such questions to have at hand a body of expert knowledge and opinion within Parliament itself is unquestionably a great advantage

But the medical members would be taking up an entirely false position—indeed, would be destroying their own influence—if they were to assume too much of an *ex cathedra* attitude in the discussion of subjects which admittedly are in their special ambit It is true that within less than a generation the science of medicine has made marvellous advances in the prevention and the curing of disease It is true also that the country realizes as never before the tremendous national service which modern medicine can give in fostering the common weal But that realization enables laymen in Parliament to take a large part in developing a policy for utilizing the newer knowledge In particular the financial aspects of every proposal must in these times be most carefully considered The anti waste stunt has fortunately subsided but the reckless extravagances and profiteerings which were perhaps largely inevitable in the war have not been forgotten and render rigid scrutiny of contemplated new outlays all the more obligatory This does not mean refusal to spend where expenditure can be demonstrated to be profitable, even if the profit be not immediate Not so long ago advocacy of casting bread upon the waters to have it returned after many days could have met with the rejoinder that before the many days had elapsed death from starvation would have occurred The country, however seems now turning on the way to recovery and can afford to take longer view The national buoyancy already in evidence is itself a sign of improving communal health, and when projects for subsidizing from public funds schemes making for public health come before the Legislature, boldness and enterprise may be the truest economy Always, however, this attitude is subject to one reservation To justify boldness necessary preliminaries are the making sure that a scheme is fundamentally sound, and that there will be no incidental evil reaction on the character of those to whom it is to be applied There is now very general recognition that the system of doles which has been so largely resorted to during prevalent unemployment tends to be most harmful to the character of many recipients It fosters both idleness and discontent The old workhouse practice of setting casual inmates to labour of little or no intrinsic value, such as oakum picking or stone breaking for which many of them were quite unfitted, was bad but at least it showed a glimmering appreciation of the evils of absolute idleness The dole policy does not even do that it fosters idleness That being perceived new methods of house building which are to diminish greatly the need for bricklaying and to provide occupation for unskilled labour are obviously on the right lines, and Parliament should not hesitate to afford them reasonable support The same principle should hold throughout the whole sphere of public assistance In questions of health the giving of aid should be accompanied by compulsion towards obedience and discipline That applies in respect of venereal disease, tuberculosis, rickets and any other conditions which are coming within the operations of State aided or rate aided schemes

We would press on the consideration of the new Government, as soon as Lord Onslow's Poor Law Commission has reported one question of the utmost public importance which has long awaited solution It is the reorganization of the whole system of local government, including the relationship of the two great departments of Poor Law and Health Apart from the county boroughs the areas for public health administration in England are as a rule absurdly too small Each of them is in the way responsible for administering (with certain exceptions) the numerous Acts relating to sanitation water supply drainage scavenging the healthiness of workshops the enforcement of building by laws the appointment of medical officers of health, sanitary inspectors and veterinary officers the supervision of meat and milk and food supply, and the control of tuberculosis acute infectious diseases and venereal disease By sheer force of circumstances voluntary agreements have been made for combined action in many adjoining areas while in respect of some matters especially institutional accommodation, the law has intervened for the creation of wider amalgamations But hand to mouth measures are made quate and incomplete Reform on national lines is urgently necessary The task should definitely be undertaken by the new Government It has all the qualifications for the purpose—sufficient time to give careful departmental consideration to the whole complicated subject and an ample majority to carry out its ultimate decisions It may meet with many difficulties particularly opposition from small local interests and prepossessions Some existing authorities, however limited their areas, and some officers, however

small then salaries, may be expected in such circumstances to offer objection to interference, but in any wise scheme care would be taken to deal tenderly with such difficulties, and a measure of national importance cannot be indefinitely postponed in deference to local sensitiveness

Britain now indulges in the hope that for at least another lustrum it will have a Government wise enough to develop a sound national policy, and strong enough to persist in it A health programme must be an essential part of that policy, and its guidance and control will require a strong and broad-minded Minister a man whose standing and reputation will inspire confidence, who will be allowed by the Prime Minister to remain in the one office long enough to set his mark, not only on the physical health of the community, but also on its character for self-reliance and independence Mr Baldwin has many great offices to fill, and he has at his disposal men qualified to do justice to most of them As years pass some departments of government lose in importance and others gain To be Minister of Health in England at the present time affords a field of work worthy of the talents and ambition and patriotism of the best man to whom the offer of the post may be made

A GENERAL VIEW OF LARYNGEAL TUBERCULOSIS

It is a common reproach of specialism that it tends to detach itself from the general commonwealth of medicine, and, by concentrating its attention on a limited area, to cultivate a small district to the neglect of the interests of the whole body politic This may be true of the more myopic exponents of a special subject, but there are others with greater range of vision It is from amongst this number that some of the most valuable additions have been made to the general knowledge of the medical profession and to its capacity to cure Of those who have thus contributed in the past the names of Hughlings Jackson and Spencer Wells rise to our memory Modern, if less striking, instances are, we are glad to say, becoming more frequent, and the Mitchell Lecture, delivered before the Royal College of Physicians of London this week, and printed at page 841, is a case in point The subject of tuberculosis of the larynx was therein dealt with by an expert, but, instead of focusing attention on local lesions and technical points—interesting and valuable to the laryngologist, but not to others—Sir StClair Thomson, out of the wealth of his experience and observation, shows the general physician the urgency of detecting the presence of developing tuberculosis in the larynx

It is scarcely too much to say that after Sir StClair Thomson's exposition no case of pulmonary tuberculosis presenting a laryngeal complication can hence forward be looked on as 'slight,' for of all the laryngeal patients he saw during ten years in the King Edward VII Sanatorium at Midhurst (early and "favourable" cases, as things are at present), no less than 70 per cent were dead within a few years Between 1911 and 1921 some 2 540 patients with pulmonary tuberculosis were discharged from that institution Of the patients found to have tuberculosis of the larynx during those ten years, two out of every three were dead by 1922, but of those with a sound larynx two out of three were still alive Another valuable lesson for the general physician is that progress or the reverse does not necessarily take place *pari passu* in the lungs and in the larynx It generally does so, but not always Hence a diseased larynx may become arrested or even heal completely while the lungs deteriorate But the converse never occurs that is to say, while the laryngeal disease is advancing no arrest of the mischief in the lungs is possible This is a very valuable prognostic point which the attendant physician might well bear in mind

In the words of the lecturer, the 70 per cent mortality among his 477 throat cases is "an arresting and a saddening thought" But it must be heed His abandonment of all local surgical measures, together with the entire armamentarium of caustics, paints, insufflations, and sprays, introduces a simpler, gentler, and more effective scheme of therapeutics He claims that the principal factor in treatment should be the sanatorium régime and a co-ordination of the study of the patient's laryngeal with that of his pulmonary and general condition As regards local care, good results were obtained from the simple method of local rest, secured by limiting the voice to a whisper, or by enforcing the more heroic rule of strict silence The only local application employed was that of the galvano cautery, which was used in 74 cases and yielded 46 cures, the method of "whispers" and "silence" arrested the disease in 73 cases These 119 arrests among 477 laryngeal cases show a cure in 25 per cent of cases, the highest proportion hitherto recorded in this country The conclusion to be drawn from these figures is in striking contrast with Morell Mackenzie's opinion forty four years ago, "it is not certain that any cases ever recover," and that of another authority of the same period, who said, in reference to patients with tuberculosis of the larynx, "all are doomed to die the appearance of the disease in the larynx is the warrant of death"

The laryngeal manifestation still remains one of the most serious complications of pulmonary tuberculosis, but Sir StClair Thomson's record of his experience gives encouragement by showing that nowadays one case in four may be arrested Still better results could be obtained by what we all invoke—early diagnosis The Mitchell Lecture throws light on this, as on many other points

THE PROGRESS OF RADIOLOGY.

Twenty-nine years ago Roentgen made his great discovery as the result of physical investigations with a Crookes's tube Since that time progress has been steady, and the value of x rays in diagnosis and in treatment has steadily increased Great improvements sprang from the discovery of a hitherto unrecognized property of radiations, and their action upon a fluorescent screen From this simple beginning a new science has grown up, and its applications to medicine have been many Diagnostic aid has been given in various branches of medicine and surgery, and radiations have been applied therapeutically to a large number of diseases For diagnosis and treatment very elaborate technique has been evolved Mechanical and physical devices have been invented for the estimation of the penetrative value of radiations, and for the establishment of a system of dosage for particular diseases

The part played in these advances by British radiologists has been noteworthy Many of the pioneers suffered grievously as a result of their devotion to the advancement of the new science, and several lost their lives A fitting memorial to those early workers—James Mackenzie Davidson, Cecil Lyster, Ironside

Bruce Archibald Reid, and others—is now approaching completion. The British Institute of Radiology (an account of which appears on another page) will, when fully equipped, commemorate the work of these men, and hold out to their successors facilities for adding still further to the lustre of British radiology.

It is but seven years since a number of radiologists, physicists and electrotherapists of this country realized the need for concerted action. To realize was to act, and almost immediately they drew up a complete scheme for the necessary teaching in the twin subjects of radiology and electrology. The University of Cambridge was approached, and with commendable foresight agreed to grant a diploma in the two subjects; courses of lectures and practical work were instituted all over the country, followed soon after by the establishment of a diploma at Liverpool. The original plans included the founding of an institute which would provide a centre for radiologists and become the co-ordinating body for this work throughout the British Empire. In 1923 this question of an institute was revived by the formation of a committee representing the Roentgen Society, the Electro-Therapeutic Section of the Royal Society of Medicine, and the British Association for the Advancement of Radiology and Physiotherapy. The late Sir Archibald Reid was the chairman of the committee at the time of his death, and it was largely due to his acumen that a suitable building at 32 Welbeck Street was acquired. Financial support for the venture was given by the trustees of the Mackenzie Davidson Memorial Fund, who handed over this fund for the purchase of the lease of the building and for the housing of the Mackenzie Davidson library. The British Association for the Advancement of Radiology and Physiotherapy by a change of name became the sponsor for the institute. It is hoped in the near future to incorporate in some way the Roentgen Society and other allied societies, so that the interests and activities of kindred bodies may find suitable headquarters in the same building.

Members of the medical profession, physicists and technicians will be welcomed at the institute either as full members or associates. It is hoped that the institute may in this way become a common meeting place where members and professional colleagues may discuss matters of mutual interest. Radiology has been regarded by some as a speciality which can and should exist alone, but radiologists insist that its greatest benefits can only come through collaboration with other branches of the profession. In furtherance of this aim it is intended to build up a collection of negatives and lantern slides covering the whole of the diagnostic field. The institute is the last of the objectives originally aimed at by the committee formed in 1917, to consider the steps to be taken to advance British radiology and to improve the status of those practising in these subjects.

INJURIES OF THE SPINAL CORD AND CAUDA EQUINA

THE committee appointed by the Medical Research Council to report upon injuries of the nervous system arising in the war has lately issued its Report No. 2 on injuries of the spinal cord and cauda equina.[1] The committee is to be warmly congratulated on the result of its labours, which forms a very valuable and interesting document. It may indeed, be hoped that this report will succeed in reaching a wide public in the medical profession, for it is much more than a mere record of the injuries of warfare. The broad lines on which the committee has wisely conceived the report have enabled it to apply the lessons of the war to the injuries and diseases of civil life. The importance of applied anatomy and physiology in diagnosis is steadily kept in view, while the disturbance in function arising from injury or disease are considered in relation to the various structural, functional, or psychical abnormalities encountered. After a brief introduction, in which the secondary importance of injuries to the bones of the spinal column is stressed as compared with the greater importance of damage to the nervous elements, a short but highly practical and informing chapter on the applied anatomy of the spinal cord follows. A discussion on the applied physiology of the spinal cord includes a useful description of the not uncommon case of unilateral injury of the cord (Brown-Sequard lesions), especially in relation to the alterations of sensation which may be found in these examples of incomplete lesions familiar to neurologists but often unrecognized by others. A careful account of the phenomenon known as "spinal shock" is given: this condition is manifested by a complete flaccid paralysis, with abolition of all reflex activity and all forms of sensation below the level of the lesion, and by retention of urine and faeces. In favourable cases—that is, in the absence of septic infection of the bladder or of bed-sores and of gross secondary changes in the part of the cord below the lesion—the effects of this spinal shock begin to pass off in from seven to ten days. It will therefore be obvious that until this shock has passed a very great difficulty will be found in deciding whether any given case is one of complete lesion of the cord or not. Though at first sight perhaps superfluous, the chapter devoted to methods of examination is one of the most valuable in the whole report, for not only are the methods themselves described, but the significance of the various signs elicited is carefully considered. The examination of the changes in the reflexes, in the power of voluntary movement, in sensation and in the functions of the bladder and rectum, is duly set out, while the added remarks on the characteristic features of hysterical paralysis and other hysterical manifestations should prove most helpful. In the committee's view the value of the tuning-fork in testing the functional integrity of the posterior columns of the cord is definitely established, and it may be hoped that this simple and useful method of examination will be more widely adopted. The actual diagnosis of spinal cord injuries is considered under three heads: (1) the distinction of organic symptoms from those of psychical origin, (2) the occurrence of organic symptoms arising from injury in cases where disease is already present in the spinal cord, and (3) the regional diagnosis or more exact localization of injuries of the spinal cord. It is hardly possible here even to summarize all the conclusions reached on these important issues. But in view of the misleading appearances often produced by different involuntary and reflex movements of the paralysed limb, as well as by the occasional return of the deep reflexes even in cases of complete transverse lesions of the cord, it is well to record the opinion of the committee that the only trustworthy signs that the cord has not been completely divided are: (1) the return of sensation and (2) the return of voluntary power. Much valuable advice on the treatment of injuries of the spinal cord is given, especially in regard to the prevention and treatment of urinary infections, the care of the bowel, and the prevention of bed-sore. The indications for laminectomy are considered, and the technique of this operation briefly described. The attitude of the committee towards laminectomy will probably be considered as distinctly conservative, but it is undoubtedly right in insisting that no useful purpose is served by operation in the early stages except in the presence of certain definite indications, tabulated as follows: (1) The presence of a gli-

[1] Medical Research Council. Report of the Committee upon Injuries of the Nervous System. II. Injuries of the Spinal Cord and Cauda Equina. London: H.M. Stationery Office. 1924. Pp. 164. 1s. 6d. net.

bony deformity or a missile demonstrated radiographically, with signs that the cord is not immediately damaged, (2) an arrest in the recovery of conduction through the damaged cord after the effects of spinal shock have presumably passed away, and (3) the presence of severe and persistent root pains It is interesting to learn that the committee finds that the old teaching—"the lower the injury the better the prognosis"—has not proved true, the records of the war show that the survival period depends more on the severity of the lesion than upon its segmental level in the cord The report treats the injuries of the cauda equina on the same plan as those of the spinal cord Thus anatomy and the motor and sensory functions are first briefly described The severe pains which often complicate these injuries are rightly emphasized, while the disturbances in the functions of the bladder and rectum and their mechanisms are explained in detail It has been found that the period of retention of urine and fæces is longer than in the cases of injury to the cord itself, but even here in favourable cases automatic micturition and defæcation may be established in from four to eighteen months after the injury A greater risk of urinary infection and a greater risk to life naturally follows The clinical picture presented by lesions of the conus medullaris very closely resembles that when the cauda equina is affected, and indeed in some examples it is not possible clearly to differentiate between them, occasionally the presence of some form of dissociation of sensation may favour the diagnosis of a conus as opposed to a cauda equina lesion While traumatic lesions of the cauda equina are generally easy of diagnosis, it is far otherwise with conditions such as tumours or chronic meningitis of the nerve roots in this region The various forms of sciatica, true sciatic neuritis, osteoarthritis of the lumbar vertebræ, for example, are all states where accurate diagnosis may for some time be very difficult The methods of examination and the interpretation of symptoms detailed in the report will be found of as much value in civil practice as they have been in the injuries of war The anterior nerve roots of the cauda equina possess a definite power of recovery which is not shared by the posterior roots, the nerves, however, the lesion is to the spinal cord the less is the prospect of regeneration A number of cases are now on record in which foreign bodies, bullets, or pieces of metal have remained embedded in the nerve roots for considerable periods of time, and the nerve roots have been in the of chronic neuritis which have largely disappeared after such removal Towards operations on the cauda equina a conservative attitude is again recommended It is very rarely possible to identify or suture any individual nerve roots, though foreign bodies can be removed and adhesions divided The report concludes with a brief description of the various orthopædic measures which may be used in the correction of the residual palsies following lesions of the cauda equina

PATENT MEDICINES

An excellent article by Sir Thomas Horder on "The scandal of secret remedies" appears in the current number of *The World Today* The author does not devote much space to proving the obvious—namely, the worthlessness of the quack nostrums that fill the advertisement columns of so many newspapers and other periodicals—but he discusses the means of remedying the scandal The law to-day is the same as it was when summarized by the Select Committee on Patent Medicines in 1914 in the following statement "For all practical purposes British law is powerless to prevent any person from procuring any drug or making any mixture whether potent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and *facsimile* signatures of fictitious physicians, and selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay" It is difficult to add anything to this simple authoritative statement, but the question is how to remedy the evil it reveals As the editor of *The World Today* observes, the quack medicine trade occupies a position of extraordinary power, for through their advertisements the proprietors largely control the press, and in this and other ways influence Parliament Ten years ago the Select Committee pointed out the crying scandal of the present state of affairs, and as the Committee prophesied, its report was allowed to drop unnoticed by the press, and for ten years nothing has been done in the matter Sir Thomas Horder mentions many other familiar examples of the power of this trade to oppose legislation adverse to its interests, and even to suppress the spread of any information *The World Today* deserves the gratitude of the public and the medical profession for publishing the present article, it is continuing the good work begun by its predecessor, *The World's Work*, which published in 1906 a scathing exposure of quack medicines Legislation on the subject of patent medicines is long overdue, for at present this particular form of fraud is positively pampered by the Legislature, but the chief remedy undoubtedly lies in educating the public The more the public know about the elementary laws of hygiene the less readily will they be exploited by quack medicine vendors, and Sir Thomas Horder points out that it is the duty and interest of the medical profession to further such education The author takes as an instance the education of the public in self-medication in the case of minor common ailments "A man will never go to a doctor for every headache that he suffers, nor every time that he is constipated—nor is it desirable that he should But the salient point is this he is surely running a much smaller risk if he attempts to correct the defect by a remedy the exact nature of which he and everybody knows, than by taking a patent medicine whose formula is secret, and may be changed from time to time without his knowledge" The medical profession, very rightly, has always been most suspicious of measures likely to encourage self-medication, but we think Sir Thomas Horder's statement of plain facts is unanswerable There are a certain number of minor ailments which the public always have treated, and probably always will treat, by themselves, and the profession ought to do its best to see that the disadvantages and dangers of this practice are minimized as far as possible by the supply of accurate information

ST LUKE'S DAY SERVICE IN TORONTO

The Toronto Academy of Medicine, the largest local medical organization in Canada, instituted this year an annual service on St Luke's Day Fellows of the Academy with their wives, together with many trained nurses from various hospitals, and a large body of medical students, assembled in the Convocation Hall of the University to the number of about one thousand Before the service began the President, Dr Harley Smith, outlined the action taken by the Academy as follows "It is fitting that we, in this daughter Dominion, loyal as we are in our devotion to the Motherland, should follow her example in many things that tend to raise us to a higher plane of living Sixty years ago some medical students in England organized a Guild of St Luke This was later extended so as to include medical graduates and associate members During all these years there have gathered in St Paul's and other cathedrals in the old land thousands of our

colleagues with students and nurses, many of them clad in academic robes, to worship the Divine Master of that disciple who, by his faithfulness in the practice of his profession and by his loving obedience to his Master, earned for himself the beautiful title of the Beloved Physician His gospel has been described as the gospel of the rejoicing spirit of God our Saviour The healing art has been recognized by the Saviour as an essential part of His work of reconciliation Three years ago the then president of the Toronto Academy of Medicine had the happy thought of instituting a similar service in our city The subject was further developed by his two successors and their respective councils, and last spring the Academy decided to hold this year the first St Luke's Day service The beautiful and appropriate order of service used on this occasion, dating back at least to the earlier half of the sixteenth century, was chosen by our immediate past-president, Dr R T Noble, in conference with the librarian of one of our theological colleges To stimulate and strengthen the members of a noble profession in faithful adherence to the highest ideals in their difficult work for mankind, and in their relations to one another, is one of the objects of our assembling to-day in this divine worship" The service was conducted by the Rev A L Rose, rector of St Mary Magdalene's Church, and the choir of the church, assisted by the Toronto University Glee Club, rendered the musical part of the service The sermon was preached by the Rev Provost Seager of Trinity College

THE ROCKEFELLER FOUNDATION IN 1923

THE annual report for 1923 of the Rockefeller Foundation[1] contains, in addition to the attractively written review by the President (Dr G E Vincent), the more detailed reports of the general director (Dr F R Russell) of the International Health Board, of the directors of the China Medical Board (Dr Roger Greene), and of the Division of Medical Education (Dr R M Pearce), the last of whom is familiar to many medical men in this country from his visits and their results During 1923 the condition of scientific medical workers in Germany was so urgent that the Rockefeller Foundation granted 194 resident fellowships, which thus provide small stipends and sums for laboratory expenses, altogether in that year the Foundation supplied 636 individuals in twenty-nine countries with fellowship funds The training of nurses has been studied and as a result active steps have been taken to facilitate a more systematic organization of education with a shorter period of instruction (twenty eight months) and the inclusion of public health in the course so as to obtain capable *staffs of visiting nurses The latest, and it is hoped the* final, bout with yellow fever in Brazil recalls the memory of Oswaldo Cruz, who, before his death in 1917, had by his efforts "made Rio de Janeiro as safe as it is beautiful" The phrase 'Parasites lost and Parasites regained," uttered by a Fijian schoolboy after listening on the same day to a talk on hookworm disease and an address on Milton, exactly describes what happens if the precautions so widely promulgated by the International Health Board are not properly obeyed Since the Rockefeller Foundation began to take a part in medical education it has helped 117 medical schools in thirty-one countries, one of the conditions being that it contributes a part only of the funds needed for a given project, with the understanding that the remainder will be provided from other sources The Peking Union Medical College, built, equipped, and maintained by the Rockefeller Foundation through the China Medical Board, is carried on by well trained men and women from many parts of the world, the seventy eight members of the medical school and hospital staffs coming from thirty-eight medical colleges in eleven different countries During 1923 there were no less than eighty-five publications from this centre in the Orient, among which special attention should be directed to Dr C W Young's account of improved method for detecting and cultivating the parasite of kala azar It is difficult to express adequately our admiration for the way in which the Rockefeller Foundation is carrying out the purpose of its charter, "the well being of mankind throughout the world"

IN OPEN BOATS

WITH the coming of the steamship and the passing of the beautiful sailing ship, the romance of the sea was considered past But now and again something happens a ship is wrecked or founders, and the old spirit of British seamanship reappears When on June 4th, 1923, the news was first flashed over the world that an open boat containing survivors from the ss *Theresa* had landed at Rodrigues Island, a sense of pride as well as relief was felt by every man and woman of our race The story has now been given to the public by Mr Cecil Foster, captain of the ship, in a book entitled *Seventeen Hundred Miles in Open Boats*[1] This plain unvarnished tale is practically the log kept by the commanders of the two open boats that carried the crew of the *Theresa* to safety—one to Rodrigues Island, the other to Mauritius It is impossible to read the account of the hardships of crews crowded into open boats—exposed to all weathers, rationed in drinking water down to the bare limit which will support life—without recalling other famous exploits in which British sailors escaped innumerable dangers in a like manner We are naturally reminded of Bligh's famous voyage, when his crew in the *Bounty* mutinied and sent their captain and the loyal members of his crew afloat in an open boat in the neighbourhood of the Friendly Islands That was in the year 1789, the voyage ending when the starved and battered heroes arrived at the Dutch island of Timor Another voyage, in many ways curiously like Bligh's was that of Captain Edwards, who commanded H M frigate *Pandora*, which sailed in 1790 to the South Seas to hunt for the mutineers of the *Bounty* and bring back for trial any they could find Edwards, who must have been a particularly hard and difficult commander to serve under, was undoubtedly a fine seaman, although he lost his ship on a reef through gross carelessness The narrative of his long voyage in an open boat, which (like Bligh's) ended at Timor, was written by his surgeon George Hamilton who was among his crew who survived the voyage this rare volume was published at Berwick in 1793 The accounts of these three voyages bring to light the fact that in each instance success was due to the stern discipline maintained by the commanding officer Food, and still more water had to be rationed to the smallest possible amount while those who broke the rule that forbade the drinking of sea water always perished Captain Foster had experienced the hardships of voyages in open boat during the war when he was more than once torpedoed by German submarines His experiences on those occasions had moved him so much that he had often discussed with his chief steward in the *Theresa* the question of how a ship's boat should be provisioned in the event of having to leave the ship on the high seas Owing to this foresight on the part of the captain he was not taken altogether by surprise when the disaster came for the steward knew exactly what provisions to put into the lifeboat The three chief items were water, condensed milk, and cigarettes The water had to be most sparingly used while generally the men

[1] *Seventeen Hundred Miles in Open Boats* By Cecil Foster Master Mariner Captain of the "Theresa" London Martin Hopkinson (Ltd (Demy 8vo pp xii—173 2 maps 2 plates 5s net)

mouths were so dry that the biscuits issued for food were seldom touched Again and again Captain Foster remarks on the benefit they all received from the cigarettes, smoking appears to have comforted and soothed the sufferers, indeed, Captain Foster, writing of this, says "When indulged in it revived everyone's spirits and added the touch of cheerfulness necessary to enable us to carry on and keep smiling" The daily ration of water allotted to every man was one-third of a cigarette tin, this was issued at 2 o'clock in the afternoon, when the worst of the heat of the day was over At 8 a m each man had a ration of milk—one cigarette-tin full—and one biscuit, and another small ration of milk in the evening While those who drank sea-water died of thirst, much relief was derived from bathing the head and body in sea-water, also from soaking the clothes in the sea, and, after partially wringing them out, putting them on again, the men who did this suffered less from thirst than those who relied only upon their ration of drinking water

AUSTRALIAN MEDICAL PUBLICATIONS

The Health Department of the Commonwealth of Australia is issuing a series of publications, under the authority of the Minister of Health, dealing with a variety of medical questions particularly as they interest the Australian practitioner The authors are all men of experience in the matters on which they have written, and all are connected with the Institute of Tropical Medicine at Townsville, North Queensland Though dealing primarily with tropical conditions as found in Australia, the subjects treated have a far wider range of application than that of a single continent, since it is by a scientific consideration of these and cognate matters that the oft-debated question of the ability of the white man to colonize and make his permanent home in the tropics will be finally decided Pamphlet No 6 of the series is concerned more directly with this problem, summarizing certain studies on acclimatization This is stated to be a preliminary communication for which the well known studies of Breinl, Young, and others, issued some years ago from the Townsville institute, form the basis Further information on this problem will be awaited with much interest Four other pamphlets (Nos 2, 3, 4, and 8) treat directly or indirectly with mosquitos No 2, a synonymic list of the more important Culicidæ of the Australian region, by Mr L E Cooling entomologist on the staff of the institute, will prove very useful for future workers, and will save much time which would otherwise have to be spent in the tedious work of 'running down" species of mosquitos No 8 by the same author, takes up the question of the bionomics of some of the commoner species mentioned in the preceding Two other issues (Nos 3 and 4) specialize on the mosquito-borne diseases, malaria and filariasis respectively There are both written by Dr Cilento, director of the institute The former is of particular importance, since this disease has hitherto proved the most vital factor in preventing the successful permanent settling of the white man in the tropics, the latter comprises a general review of the subject of *Filaria bancrofti*, the parasite, the diseases to which it gives rise and their treatment, compiled from the standard textbooks and reports Pamphlet No 5, on the diagnosis of bowel diseases, is likewise mainly a compilation, though a valuable one It deals with the prevalence of intestinal affections in Australia, dividing them into three main groups helminthic, in particular ankylostomiasis, sprue, consisting largely of extracts from Dr Manson-Bahr's writings, and the dysenteric group, amœbic and bacillary The final pages, on helminthological matters, need considerable revision in the light of more recent work Even though these publications contain little or no new matter, they will doubtless be very useful for the practitioner in Australia, for whose benefit they have been written They will not only save him time in looking up points in larger text books, but they indicate when it is necessary or advisable to send material for special examination, they tell him how to take the specimens and how to interpret and evaluate the reports he receives from the laboratories Though the issues before us consist largely of compilations they form an excellent foundation for the erection of a superstructure of new material, and if the standard is maintained when dealing with special subjects the series should in time prove as valuable as the publications of the Washington Bureau, and be as widely read

GOLD TREATMENT OF TUBERCULOSIS

For some time past Professor Holger Mollgaard and his fellow workers in Copenhagen have been investigating the direct chemical action of gold salts upon the tubercle bacillus At a meeting of the Danish Medical Society held in Copenhagen on October 28th Professor Mollgaard gave a preliminary account of the experimental work and the clinical results, and we understand that full details are now in course of publication in book form in English The method is a form of chemotherapy A solution of the gold salt is injected intravenously or intramuscularly Its destructive action on the tubercle bacillus appears to liberate a toxin, often with serious results to the patient To neutralize this reaction a protective serum obtained from an immunized horse is administered beforehand The constitution of the gold salt is said to be such that the risk of metallic poisoning is slight Arrangements have been made for producing it in bulk in Denmark under the name "sanocrysin," but we understand that Professor Mollgaard is not making it generally available at present He has asked the Medical Research Council to organize the investigation of its properties in this country The new method of treatment is obviously one which should only be applied with great care, and with full knowledge of the laboratory and clinical tests already made

The three hundredth anniversary of the birth of Thomas Sydenham will be commemorated at a meeting of the President and Fellows of the Royal College of Physicians of London at the College, Pall Mall East, on Wednesday next, November 12th There will be a reception at 8.30 p.m., followed by a short address by the President, Sir Humphry Rolleston, Bt., K.C.B.

The Schorstein Memorial Lecture will be delivered by Sir Arthur Keith, F.R.S., in the anatomical theatre of the London Hospital Medical College on Wednesday, December 17th, at 4.15 p.m., the subject chosen is the clinical importance of the bulbus cordis The lecture will be illustrated by lantern slides Members of the medical profession are cordially invited

By an Order of the Privy Council, Professor E. P. Cathcart, C.B.E., M.D., D.Sc., F.R.S., Professor of Chemical Physiology in the University of Glasgow, has been appointed a member of the Medical Research Council in the place of Professor D. Noel Paton, M.D., F.R.S., who has retired

Dr. Herbert R. Spencer will deliver the second David Lloyd Roberts Lecture on the renaissance of midwifery, illustrated by books and lantern slides, on Wednesday, November 19th, at 5 o'clock, at the house of the Medical Society, of London, 11, Chandos Street, Cavendish Square

BRITISH INSTITUTE OF RADIOLOGY

In the diagnosis of disease radioscopy and radiography are being increasingly employed, and it is also recognized that radiotherapy constitutes a great advance in the treatment of many kinds of disease. Still greater progress would become possible at closer and more intelligent co-operation could be effected between radiologists and medical practitioners on the one hand, and between radiologists, physicists, and technicians on the other. The interest of medical practitioners generally would be deepened and their more effective co-operation secured if convenient opportunities were afforded them of observing the improvements that are being made in the application of radiology to diagnosis and treatment.

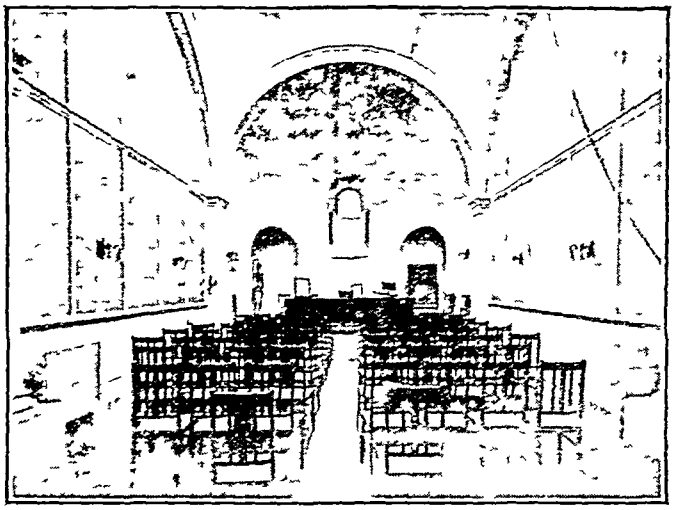

FIG 1.—The Lecture Hall—old church of the Russian Embassy.

Isolated radiologists often encounter problems the solution of which is rendered difficult by the want of necessary apparatus and advice. Comparison of technique and methods is necessary, and facilities are very desirable for testing suggestions made by workers who though in actual practice have inadequate laboratory equipment. The practice of radiology is inevitably associated with the use of apparatus, upon the efficiency of which the excellency of the work must depend. If the manufacturer of this apparatus is clearly aware of the requirements of the medical radiologist, and of the nature of any projected research, he could in many cases make valuable suggestions and provide the necessary facilities. Consultation between the two would result in improvements in the design and detail of apparatus, which would lead to further advances in diagnosis and treatment. In this country there has been so far less co-operation between technicians, physicists, and medical radiologists than in other countries and it is indisputable that the British prestige in such matters would be enhanced by the mutual association made possible by a central institute the membership of which would combine representatives of all the interests involved and through which a general co-ordination of individual efforts could be established.

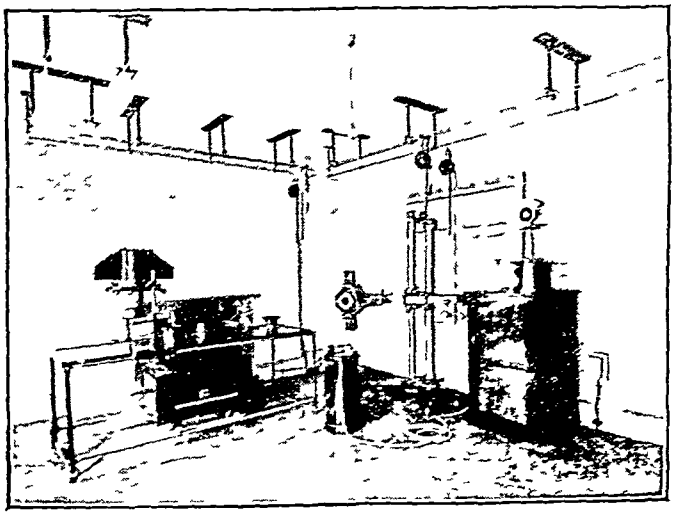

FIG 2.—A corner of the Demonstration Room.

Origins and Aims of the Institute

In the spring of 1923 a committee, under the chairmanship of the late Sir Archibald Reid, was formed for this purpose, representatives being included from the Royal Society of Medicine, the Roentgen Society, and the British Association for the Advancement of Radiology and Physiotherapy. This committee having considered for some time the establishment of a central organization along the lines just indicated, resolved to found a British Institute of Radiology, and issued a preliminary and limited appeal for funds. The nucleus of a library had already been provided by Lady Mackenzie Davidson, who had presented to the Institute the valuable collection of books which had belonged to her husband. In addition to this a definite status had been conferred upon the Institute by the action of the trustees of the Mackenzie Davidson Fund in handing over to the organizing committee of the Institute the sum of money collected. With this money the purchase price of the lease of 32, Welbeck Street, London was paid and it was estimated that the completion of the equipping of the premises would involve a further initial expenditure of about £2,000, towards which there was a balance from the Mackenzie Davidson Fund of £300. Sir Archibald Reid was actively engaged in the detail of the work of establishing the Institute when his death last January deprived the organization of a great driving force.

In April 1924, articles of association of the British Institute of Radiology were adopted and confirmed with the sanction of the Board of Trade, this being achieved by the alteration of title of the pre-existing British Association for the Advancement of Radiology and Physiotherapy, among whose main objects had been the formation of such an institute.

The objectives of the British Institute of Radiology are as follows: (*a*) to promote the advancement of radiology and physiotherapy on scientific lines under the direct control of the medical profession, protecting in every way possible the interests of those engaged in these subjects; (*b*) to effect legislative improvements in this connexion; (*c*) to provide for the delivery of lectures, the holding of classes and examinations, the establishment of scholarships and the granting of prizes, diploma and certificates, (*d*) to arrange for the publication of papers, communications, or treatises, (*e*) to promote and provide for research in experimental work, and to establish, grant, and award in connexion therewith, (*f*) to establish and maintain

a library and museum, and to organize exhibitions of apparatus, (*g*) to establish charitable and benevolent funds for the benefit of persons engaged in radiology and physiotherapy

Equipment of the Institute

The property in Welbeck Street includes the old church of the Russian Embassy, which has now been adapted to serve as a lecture hall Heating apparatus has been installed, and a special lining has been applied to the walls so as to improve the acoustics A smaller lecture room has been equipped with desks and accommodation for the Mackenzie Davidson memorial reference library Another room has been fitted with apparatus for demonstration purposes, and part of the extensive cellars will be available for individual research work The problems of diagnostic technique and the physics concerned in radiology provide also opportunities for research Examples of improvements in apparatus will also be exhibited as they are devised With a view to establishing the possibility of comparing the results of different workers it is hoped that some form of standard technique may eventually be adopted Developing tanks have been installed in a small room, and an ingenious arrangement provides for the exclusion of light even when the door is open A handsomely decorated room on the ground floor is available for committee meetings and meetings of affiliated societies In memory of Sir Archibald Reid a reference collection of radiograms is being established, this was a matter in which he took very great interest during his life Radiograms of normal conditions, as well as of such diseased conditions as osteomyelitis, tuberculosis, and bone growths, will be carefully collected, and duplicate sets will be prepared for the use of medical schools or individual lecturers where facilities exist for their demonstration Lantern slides of these radiograms will also be prepared, and will be available for loan These lantern slides will be of great value in radiological teaching in medical schools, and it is probable that a syllabus of lectures will eventually be drawn up The Institute also will be able to provide medical post-graduate courses and classes for the makers of radiological apparatus and their assistants

It is proposed to hold an International Congress of Radiology at the house of the Institute in the summer of 1925, when it is suggested that four days should be employed in discussions, and subsequent visits should be arranged to provincial centres It is hoped that an international committee may result from the congress, and that a permanent nucleus for international collaboration on radiology and kindred subjects will be so initiated

An appeal has just been issued on behalf of the British Institute of Radiology asking for a sum of £6,000 to pay off the bank loan of £2,000 and to provide a nucleus for further development Donations are invited to the general foundation fund or for the Reid memorial collection The subscription for membership of the Institute, including receipt of the *British Journal of Radiology*, is 3 guineas annually, and there is a fee of 1 guinea payable on entrance, the subscription for life membership is £30, associates pay 10s 6d on entrance and £1 11s 6d annually

THE GENERAL ELECTION

Medical Members of the New Parliament

The following five medical men who were members of the last Parliament have been re-elected to the House of Commons at the recent general election

Dr Walter E Elliot, M C (C), Glasgow, Kelvingrove
Dr F E Fremantle, O B E (C), St Albans
Dr L Haden Guest (Lab), Southwark North
Professor Thomas Sinclair (C), Queen's University, Belfast Returned unopposed
Dr J H Williams (Lab), Llanelly

New Members

The following six members of the medical profession have also been elected, two of whom have already sat as members of the House of Commons

Sir Henry Jackson (C), Wandsworth Central
Dr E Graham Little (Ind), University of London
Sir Richard Luce, K C M G (C), Derby
Dr A Salter (Lab), Bermondsey West

Dr Salter was elected for Bermondsey West at the November, 1922, election, but was unsuccessful in the 1923 election

Dr Thomas Drummond Shiels, M C (Lab), Edinburgh East
Dr T Watts (C), Manchester, Withington

Dr Watts was elected for the Withington Division of Manchester in November, 1922, but was defeated at the 1923 election

The Scottish Universities

The polling for the combined Scottish Universities (three seats) will not close till 10 a m on Tuesday next At the last election two Conservatives and one Liberal were returned unopposed—namely, Sir Henry Craik, K C B, and Sir George Berry, F R C S Ed (Conservatives), and Mr D M Cowan (Liberal) It is to be hoped that all medical practitioners who have votes in this constituency will take their part in the election for which there are several new candidates Sir George Berry is the only medical man standing, but it will be remembered that Sir Henry Craik is an honorary member of the British Medical Association and a valued friend of Medicine in Parliament

Unsuccessful Candidates

The following four medical men who sat in the last Parliament were defeated at the polls—namely Dr W A Chapple (L) Dumfriesshire, who represented Stirlingshire from 1910-18 and Dumfriesshire since 1922, Mr Somerville Hastings (Lab) was elected in 1923 to represent Reading, Dr G E Spero (L), Stoke Newington, who, after being an unsuccessful candidate at Leicester in the 1922 contest, was elected to represent Stoke Newington in 1923, Lieut-Colonel T S Beauchamp Williams (Lab), Kennington, who was elected in 1923 to represent the Kennington Division of Lambeth

The following members of the profession were also unsuccessful Several of them had previously represented or contested either the same or other constituencies

The Right Hon C Addison (Lab), Hammersmith South
Dr Ethel Bentham (Lab), Islington East
Sir John Rose Bradford (C), University of London
Dr F G Bushnell (Lab), University of London
Dr Stella Churchill (Lab), Hackney North
Dr R Dunstan (Communist), Birmingham West
Dr O Gleeson (Lab), Portsmouth North
Dr J J Lynch (Ind), Walsall
Dr I H MacIver (Lab), Argyllshire
Dr R O Moon (L), Oxford
Dr H B Morgan (Lab), Camberwell North West
Dr Joseph Robinson (Lab), Stretford
Dr Laura Sandeman (C), Aberdeen North

Polling Figures

The following are the polling figures at all the contested elections in which there were medical candidates on October 29th The names of the medical representatives are printed in italics, and an asterisk denotes that the candidate sat in the last Parliament

Glasgow, Kelvingrove	
*Dr *Walter E Elliot, M C* (C)	18 924
F Kerr (Lab)	12 844
Conservative majority	6 080
St Albans	
*Dr *F E Fremantle* (C)	18 004
Frank Herbert (Lab)	8 682
Conservative majority	9 322
Southwark North	
*Dr *L Haden Guest* (Lab)	8 115
I A St John (L)	7 089
J J Llewellin (C)	3 566
Labour majority	1 026
Wandsworth Central	
Sir *H Jackson* (C)	13 231
C Latham (Lab)	8 252
Conservative majority	4 979
University of London	
Dr *E Graham Little* (Ind)	7 [illegible]
Sir *J Rose Bradford* (C)	2 813
Prof. or A E Pollard (L)	1 533
Dr *E C Bushnell* (Lab)	1 037
Independent majority	[illegible]

DERBY
Right Hon J H Thomas (Lab) 27 23
Sir Richard Luce (C) 25 25
*W R Raynes (Lab) 25 172
Mrs E J Hulse (C) 21 00
J H Stewart (L) 7 083
Labour majority 2 251
Conservative majority 253

BERMONDSEY WEST
Dr A Salter (Lab) 11 518
*Rev R M Hedward (L) 8 616
Labour majority 2 902

EDINBURGH EAST
Dr T Drummond Shiels (Lab) 9,350
C Milne (C) 6 105
J M Hogge (L) 5 625
Labour majority 3 225

MANCHESTER WITHINGTON
Dr T Watts (C) 13 633
E D Simon (L) 10 475
E Whiteley (Lab) 2 467
K Burke (Ind) 2,6
Conservative majority 3 158

LLANELLY
Dr J H Williams (Lab) 20,516
R T Evans (L) 18 257
Labour majority 2 259

HAMMERSMITH SOUTH
Right Hon Sir William Bull (C) 12 619
Right Hon C Addison (Lab) 8 804
E Welton (L) 1 383
Conservative majority 3 875

ILLINGTON EAST
Major R Tasker (C) 14 144
Dr Ethel Bentham (Lab) 10 280
*A S Comyns Carr (I) 7 406
Conservative majority 3 894

DUMFRIESSHIRE
General J Charteris (C) 12 718
Dr W A Chapple (L) 8 472
Mrs A Dollan (Lab) 6 342
Conservative majority 4 246

HACKNEY NORTH
Captain A Hudson (C) 11 915
J H Harris (I) 7 181
Dr Stella Churchill (Lab) 6 087
Conservative majority 4 734

BIRMINGHAM WEST
Right Hon Austen Chamberlain (C) 14 801
Dr R Dunstan (Communist) 7 158
Conservative majority 7 643

PORTSMOUTH NORTH
Major Sir Bertram Falle (C) 17 597
Dr O Gleeson (Lab) 10 279
Conservative majority 7 318

READING
H G Williams (C) 21 358
Mr Somerville Hastings (Lab) 18 337
Conservative majority 3 001

WALSALL
W Ireton (C) 15,168
Pat Collins (L) 12 734
Captain L Small (Lab) 11 474
Dr J J Lynch (Ind) 622
Conservative majority 2 434

ARGYLLSHIRE
F A Macquisten (C) 9 2 0
Right Hon Sir W Sutherland (L) 6 211
Dr I H Maclver (Lab) 4 532
Conservative majority 3 029

OXFORD
R C Bourne (C) 12 196
Dr R O Mson (I) 6 8.6
F Ludlow (Lab) 2 260
Conservative majority 5 3?0

CAMBERWELL NORTH WEST
F T Campbell (C) 9 626
Dr H B Morgan (Lab) 9 432
*Right Hon T J Macnamara (L) 5 L8
Conservative majority 194

STRETFORD DIVES
Sir T Robinson (L) 20 826
Dr Joseph Robinson (Lab) 11 520
Liberal majority 9 ,06

ABERDEEN NORTH
F Roose (Lab) 13 2 9
Dr Laura Sandeman (C) 8 5..
Labour majority 4 704

STOKE NEWINGTON
H G Jones (C) 10 688

George Harvey (C) 14 8-3
Lieut Colonel T S Beachamp Williams (Lab) 11 572
Conservative majority ?,6

England and Wales.

RABIES IN ENGLAND AND WALES

On July 12th, 1919 (p 50), we referred to the issue by the Ministry of Health of a revised memorandum on the procedure to be adopted in the case of a person bitten by a dog suspected or being rabid The Minister of Health has now stated that in view of the disappearance of this disease in England and Wales, no case having occurred since December, 1921, he has decided that special arrangements for antirabic treatment are no longer necessary A further revision of the memorandum with regard to treatment has therefore been issued, and it is announced that arrangements may still be made with Professor Dudgeon (Department of Pathology, St Thomas's Hospital, S E 1) for antirabic treatment with carbolized vaccine prepared at the Ministry's laboratory The cost of the treatment and other expenses must be borne by the patient or by local sanitary authorities The centres for treatment at Plymouth, Cardiff, Birmingham, Manchester, and Newcastle upon-Tyne have accordingly been closed In the revised edition there is no other radical change, as compared with the earlier memorandum, and the concluding paragraph repeats the injunction to use all possible expedition in following the procedure laid down

FINANCE OF LONDON HOSPITALS

Under the direction of the Hospital Economy Committee of King Edward's Hospital Fund for London, a statistical report has been published based on the accounts of 116 hospitals and on returns made to the Fund General particulars of the work and accommodation in these hospitals are given, and their incomes and ordinary expenditures are analysed so that the cost of working in respect of the more controllable items of expenditure can be estimated The tables which deal with working costs will assist hospital managers in controlling expenditure and in avoiding increases in cost which are not associated with increase in the quantity or quality of the work The expenditure in each hospital is compared with the expenditure in other hospitals and with the average of those hospitals with which it is most comparable Increases common to all hospitals can thus be distinguished from those peculiar to any particular institution Hospital managers may in this way find out whether at their own hospitals the cost appears to be unduly high, and, if so in what departments the cause of the excess is present They can thus reduce it wherever it cannot be justified, and so carry out one of the recommendations of Lord Cave's committee for the re establishment of the finances of the voluntary hospital system In a general review of hospital work it is stated that between 1921 and 1923 there was an increase in the available beds of 360 but a decrease in the average occupied beds of 130 leaving a net increase in 1923 over 1913 of 1 200 available beds, and 330 average occupied beds This contrast is due to several causes the chief of which was that six hospitals, aggregating 542 beds were entirely closed to in patients during 1923 for periods ranging from three to ten months Between 1921 and 1923 there was an increase of 3,600 new patients, resulting in a net increase in 1923 over 1913 of 22 600 The patient rate per bed also increased in 1913 it was 14 3 in 1921 15 5, in 1922, 15 6 and in 1923 16 This increased rate of work may be stated in another way—namely that the average duration of stay for each patient fell from 25 5 days in 1913 to 23 5 in 1921 and 22 8 in 1923 The income of the 116 hospitals apart from special distributions—as for instance emergency grants from the King's Fund and from the National Relief Fund—increased from £2,415,000 in 1922 to £2 857 000 in 1923 An outstanding feature of this last year was the large total of legacies which aggregated £473 000 of this £247 000 came from a single source Discounting such factors however it may be stated that since 1920 the income of these hospitals from normal sources shows a steady increase The hospital expenditure in 1923 was £2 630 000 an increase of £40 0 0 over 1922, but representing a considerable drop since 1917

when the figure was £2,813,000 From the figures of hospital work set out it is obvious that the greater part of this fall in expenditure is not due to decrease in the volume of work, but to reduction in cost The most critical year for the voluntary hospitals in London was 1920, when the gap between income and expenditure was at its widest The improvement, which began in 1921 and continued in 1922, is shown to have bridged the gap in 1923, when, for the first time in the post-war period, the total general fund expenditure, taking the hospitals as a whole, was met out of the revenue of the year from normal sources The improvement may also be indicated by taking the figures of surpluses and deficits separately Thus in 1922, 60 hospitals had surpluses for the year amounting to £67,000, and 56 had deficits amounting to £242,000, while in 1923, 62 hospitals had surpluses amounting to £382,000, and 54 had deficits amounting to £155,000

The London County Council Mental Hospitals

During the three months ending September 30th the number of new patients admitted to the nine mental hospitals under the control of the London County Council was 794, and the number transferred to them from some other institution 195 During the same period 218 patients were discharged recovered, 168 relieved, and 219 died The number on the register on September 30th was 18,374 At Maudsley Hospital the number of private boarders admitted during the quarter was 103, 90 were discharged, 13 died, and the number remaining in residence is 135 In the out-patients' department of this hospital 197 persons (64 men, 117 women, and 16 children) have received treatment since its opening The London County Council has given permission for the Eugenics Education Society to take photographs at mental institutions for use in the production of a "eugenic film" for educational purposes These photographs are to contain no recognizable portraits of patients

Salaries of L C C Medical Officers

The London County Council Establishment Committee is recommending that the maximum basic salary of three principal assistant medical officers should be increased by £100 a year, making the scale in each case £700, rising by annual increments of £50 to £1,000 a year (instead of £900 as hitherto), based on pre-war conditions This last provision means that a salary nominally of £1,000 a year will be subject to temporary additions making it at the present time £1,219 The officers concerned are Dr McC Wanklyn, Dr J A Brincker, and Dr N D Bardswell, and in regard to their work the following considerations are put forward by the committee The first officer is concerned with general public health matters, in particular in connexion with small-pox, typhus fever, etc, and it is pointed out that the task of safeguarding the population of London against the introduction of such diseases from abroad has become much more onerous owing to the existing conditions on the Continent and the removal of migration restrictions which existed during the war The second officer is in charge of the bacteriological laboratory and the control of infectious diseases in schools The demands on the laboratory have increased with the development of the school medical service and the opportunity afforded by a large staff of school doctors for the more frequent visitation of schools The third officer has to do with the administration of sanatorium benefit and must necessarily be an expert in the diagnosis of tuberculosis and a clinician of the first rank

Central Association for Mental Welfare

The Board of Education issued on September 12th a circular (No 1341) in which important suggestions were made regarding the supervision of defective children up to the age of 16 and their further protection after that age The Central Association for Mental Welfare has just issued a memorandum to local education authorities drawing special attention to this circular and offering its help in the carrying out of these suggestions The branches of the Mental Welfare Association are mainly concerned in the care of defective children and adults in their own homes This care is exercised in the following ways (1) friendly visits in the home of the defective, (2) advice to the parents as to the best methods of training and teaching, (3) teaching the defectives simple handicrafts, (4) systematic inquiry as to possible employment for defectives in the area, and supervision of defectives when employed, (5) providing occupation centres for young defectives These centres are arranged for defective children excluded from special schools notified to the local control authorities, defective children of the lower feeble-minded grade excluded from elementary schools but for whom no special school is available, young defectives over 14 unemployable in ordinary industries Fifty of these centres have already been established by local mental welfare associations and have given ample proof of success The administrative machinery for carrying out this work is simple, efficient, and economical A small voluntary committee composed of representatives of authorities (local education authorities, mental deficiency committees, and Poor Law guardians) and of societies engaged in social work is formed A paid secretary and visitor is appointed and a paid supervisor for occupation centres where these are opened Payments for such committees are received from the local education authorities In addition, special grants are received from the Board of Control and the local authority under the Mental Deficiency Act for the expense of the occupation centre

The association desires to assist local authorities in forming local mental welfare associations The honorary secretary, Miss Evelyn Fox, will be glad to visit any area where the authorities are considering plans for carrying out the suggestions in the Board's circular and to explain the methods to be adopted The association has also a staff of competent organizers whose services can be placed at the disposal of any authority for organizing and starting the work The charge merely covers the salary of the organizer for the time being (at the rate of about £5 per week) and out-of-pocket travelling expenses The organizer can also train a local worker to take up the permanent post Two points are specially emphasized the local Mental Welfare Association would work under the direction of the responsible officers of the authorities from whom payments are received, thus avoiding any overlapping, co-operation with the mental deficiency committees ensures the continuity of care of the individual defective from childhood onwards The memorandum is signed by Sir Leslie Scott, K C, M P (President), Dr H B Brackenbury (Chairman, Education Committee), Dr A F Tredgold, and the Honorary Secretary It is to be hoped that all education authorities in whose areas there is not a local association for mental welfare will welcome the help and co-operation of the Central Association in establishing these

Appointments at the Bristol Royal Infirmary

Dr Stuart Hardy Kingston has been appointed dermatologist to the Bristol Royal Infirmary This is a new post Formerly one of the physicians had charge of skin cases as well as medical Dr J A Nixon resigned the skin department on being appointed professor of medicine in the University of Bristol, but remains physician at the Infirmary Mr Eric Watson-Williams, M C, M Ch, son of Dr P Watson-Williams, has been appointed assistant surgeon to the ear, nose, and throat department

Scotland.

University of Edinburgh

At a meeting of the General Council of Edinburgh University, held on October 31st, Principal Sir Alfred Ewing reported that the number of students who had matriculated for the year 1924 up to date was 3,541, as against 3,379 at the corresponding date last year There was a definite reason for this increase this year, for the first time, a penalty was attached to those who did not matriculate before the end of October At the same time he did not think that the figures showed there was going to be any large falling off in the total numbers for the coming session as compared with last session At a graduation ceremony, held in the Old University on October 27th, the Principal referred to the loss which the University had

sustained by the death of Professor Alexis Thomson (Surgery) and Professor Hunter (Public Health) in the Faculty of Medicine He also referred to the fact that during the past year the number of matriculated students had included 1,195 women A great social change was indicated by the comparatively large number of women now entering the University and by the fact that there was not a single faculty in which women were not represented, even in the Faculty of Divinity during the past year there had been two women students The falling off of students in the Faculties of Medicine and Science had been serious, although there had been an increase in the Faculty of Arts to balance this The decrease in numbers was, however, a serious financial loss to the University, which had necessitated reduction of the staff and the making of other small economie

New Professor of Surgery in Glasgow

The governors of the Anderson College of Medicine, Glasgow have appointed Mr James Russell MB, FRCS to the chair of surgery in the Anderson College rendered vacant by the appointment of Professor Young to be *Regius Professor of Surgery in the University of Glasgow*

Glasgow University Medico-Chirurgical Society

At the opening meeting of this society Lieut General Sir William Leishman Director General of the Army Medical Department, delivered an address to the students on 'The army as a field of medical research" He referred to the high place taken by Glasgow students in research work in the army and elsewhere, and emphasized the fact that such work was not necessarily confined to the laboratory He described the various kinds of research work carried on in the army under peace conditions, and outlined the training necessary for such work

Aberdeen University Rectorial Election

The election of a Lord Rector for Aberdeen University takes place to day (Saturday, November 8th) The candidates nominated are the Viscount Cecil, KC, who has been nominated by the Unionists, Lord Meston of Agra, a former pupil of Aberdeen Grammar School and alumnus of Aberdeen University, who has been nominated by the Liberals because of his distinguished career in the Civil Service and the Right Hon C P Trevelyan, MP, Minister of Education under the Labour Government who has been nominated as Labour candidate The retiring Rector is the Right Hon Sir Robert Horne, KC, MP, a former Chancellor of the Exchequer

Physical Training in Scottish Schools

The Carnegie Dunfermline Trustees, at a meeting last week, had before them a report from the Committee of the Dunfermline College of Hygiene and Physical Education regarding an important development in the work of the college For some years the Trustees have offered facilities to qualified male teachers to take a course of one year at the college and so add a qualification in physical training to their general certificate, but until the present year this course had attracted no applicants Last month the Glasgow Education Authority, in view of the lack of suitable instructors of physical education, had agreed to give a year's leave of absence to seven of their staff in order to enable them to proceed to the Dunfermline College for the *purpose of taking this one year's course in physical* training It was reported to the Trustees that several other education authorities had the matter under consideration and it is expected that some of these will follow the example set by the Glasgow authority

Care of the Feeble-Minded in Scotland

The fourth annual conference of the Scottish Council of Women Citizens' Associations was held last week at Falkirk At the concluding meeting Lady Leslie Mackenzie chairman of the Council moved a resolution that the establishment throughout Scotland of residential industrial communities for the permanent care of the feeble minded should be taken in hand without delay She felt that the time had come for the women of Scotland to band themselves together to secure the rectification of defects in civilization so that *people who could not care for themselves* should be permanently cared for This did not affect the insane but that class of people who were born with mental defects and who could not develop sufficiently no matter how much education and training they were given In 1906 an Act had been passed by Parliament allowing school board to educate the children in special school but this protection stopped at the age of 16 years, when they were turned out into the world Some of them got employment which they were able to hold only for a short time with the result that many gravitated to poor houses or penal institutions instead of leading lives which might be made useful, happy and safe in a normal environment A colony system had been established in several English counties, under which mental defectives of all ages were kept under permanent supervision and given work for which they were suited Such colonies had also been established experimentally in other countries The Women Citizens' Council had decided to collect sufficient money for the establishment of such a colony in Scotland and it was a work which women should be proud to undertake Dr R D Clarkson Medical Superintendent of the Royal Scottish Institution for the Feeble minded at Larbert seconded the motion He said that thirty years of experience in this work had convinced him that on the solution of the problem of the feeble minded the solution of many other social problems depended Feeble minded persons turned loose in the community became drunkards, paupers, and inmates of rescue homes their condition then became incurable The institution at Larbert had been established over sixty years ago mainly by philanthropists and doctors who thought that by such education for five or six years mental defectives might be transformed into normal citizens After many years of experiment however, it was found that if a child was mentally defective it would remain so for life and the best thing for many of them was to be kept in institutions or colonies all their lives where they could be trained for some particular work in the colony and could be drafted out for work in the fields and for hand work of various kinds, thus diminishing the cost of their maintenance Teaching mental defectives was a matter requiring a special gift not necessarily of an intellectual type Many mental defectives were well adapted to look after persons more feeble-minded than themselves and would go on doing it for years without feeling it so great a burden as it would become to more *highly strung people* Plenty of work would be found for a colony if one were to be established The motion was unanimously carried

West of Scotland Foreign Service Medical Club

The sixth annual meeting and dinner of this club was held in the Grosvenor Restaurant Glasgow on October 28th under the presidency of Lieut-Colonel John McKie, DSO TD The large gathering included the following as guests Major-General H L Reed VC CB CMG, General Officer Commanding 52nd (Lowland) Division, Lieut Colonel G H Rae Gibson DSO East of Scotland Overseas Medical Club Dr W T Gairdner MC honorary secretary East of Scotland Overseas Medical Club Major J D Richmond DSO OBE Senior Medical Officer Maryhill Barracks Glasgow After the toasts of "The King" and 'Our Fallen Comrades" had been given from the chair the toast of The Club was proposed by Lieut Colonel George Gibson of Edinburgh in a humorous speech to which the President suitably replied General Reed expressed appreciation of the work of his comrades in the RAMC and of the large body of practitioners who served in the great war A varied musical programme added greatly to the enjoyment of the evening and to this Drs Laird Wright Thomson Wallace Anderson Gibson, Gardiner Templeton McKie Adam Burns and Scouller Buchanan contributed Officers were appointed for the year as follows President Dr John M Corran, Vice-President, Dr W B Armstrong, Honorary Secretary and Treasurer, Dr David Shannon

Central Midwives Board for Scotland

At a meeting of the Central Midwives Board for Scotland for the hearing of penal cases, Dr Michael Dewar, deputy chairman, presiding, a certified midwife appeared in answer to charges of negligence and breaches of the rules and also failure to notify immediately a case of ophthalmia neonatorum, which were found proved. In order to give her an opportunity of proving amendment, sentence was postponed for reports at the end of three months from the local supervising authority on her conduct and methods of practice, and also at the end of six months. Failing satisfactory reports being received the secretary was instructed to remove her name from the roll.

Nurses' Examination in Scotland

The number of nurses who presented themselves for the preliminary examination in all subjects held recently by the General Nursing Council for Scotland was 94, of whom 69 passed in anatomy and physiology, 70 in hygiene, and 77 in elementary theory and practice of nursing. In addition, a number of candidates who had failed at a previous examination presented themselves again, and of those 21 passed in the subjects for which they appeared.

Co-operation in Chemistry

The first joint meeting for the present session of the Edinburgh and East of Scotland sections of the Institute of Chemistry and of the Society of Chemical Industry was held on October 22nd in the hall of the Pharmaceutical Society, York Place, Edinburgh, Dr Alexander Lauder presiding. An address was delivered on "Co-operation in chemical science" by Mr W. J. Woolcock, C.B.E., President of the Society of Chemical Industry. The lecturer especially dealt with the activities of various chemical societies which had organized exhibits in the industrial section of the British Empire Exhibition, and he pressed for a closer co-operation between chemists and those who develop chemistry in the various industries, with a view to the mutual advantage of both types of activity.

Correspondence.

TONSILLECTOMY

SIR,—The three resolutions regarding tonsillectomy passed unanimously at the meeting of the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association (BRITISH MEDICAL JOURNAL, November 1st, p. 813) are presumably idealistic, but the first resolution, at any rate, surely goes too far. It says that tonsillectomy by enucleation is the only efficient operation in dealing with tonsillar disease."

Tonsil enucleation came into vogue only towards the end of the twelve years during which I was in charge of the throat department at Guy's, but I refuse to believe that every one of the hundreds of tonsil operations, excepting those of enucleation, for which I was responsible was a failure. As a fact I know that this was not so, and it must be common knowledge that enormous numbers of patients have been cured of their throat troubles by partial removal of their tonsils with a guillotine. Of course there are failures, but so also are there failures after enucleation. Unsuspected remnants have given rise to further troubles after the operation in a few of my own cases, and I have been consulted on various occasions by patients whose tonsils well-known laryngologists had failed to completely enucleate.

Tonsillectomy by enucleation is therefore not the *only* efficient operation, although it is without doubt the *most* efficient.

But even if the most efficient is it in all circumstances the most desirable? Is the practitioner—whoever and wherever he be—to feel that he is in duty bound to attempt the major operation of enucleation rather than the minor one of guillotining, when called upon to treat cases of hypertrophied tonsils? In my humble opinion this would be asking too much, and would certainly result in an increase in the proportion of unsatisfactory results. It may, of course, be argued that tonsils should only be removed by those specially skilled in the operation of enucleation. This is perfectly correct, but I doubt whether there is a sufficiency of skilled operators for the work, further, it must be remembered that many of these operations are, and always will be, undertaken by those who no doubt do their best but who have no great amount of skill.—I am, etc.,

London, W.1, Nov. 3rd. F. J. STIWARD.

TREATMENT OF EXOPHTHALMIC GOITRE WITH INSULIN

SIR,—The idea of treating hyperthyroidism with insulin, described in the important paper by Dr. R. D. Lawrence in the JOURNAL of October 25th (p. 753), has probably occurred to many clinical physicians. During the latter part of 1923, and in the earlier months of this year, I used insulin in the treatment of three such cases. In one of them the hyperthyroidism was associated with the presence of adenomata of the thyroid, and no improvement resulted, the other two cases both improved to a remarkable degree, but as the improvement was estimated purely on clinical grounds I could not consider that insulin had been shown to be the decisive factor in the treatment. I was sufficiently impressed, however, with the possibilities of insulin in this connexion to resolve that at the first opportunity I would treat a case of acute Graves's disease with it. A recent experience has so completely confirmed this impression that I venture to record the particulars at some length.

On October 19th (before the publication of Dr. Lawrence's paper) I was asked by Dr. A. W. Weston of Dudley to see a woman of middle age who, three weeks previously, had developed acute exophthalmic goitre. One of her sisters had died of the same disease and mother, I am told, has hyperthyroidism. When I first saw the patient she was almost maniacal, she moaned and cried incessantly and threw herself continually about the bed, incoherently complaining of violent upper abdominal pain. Vomiting was frequent and distressing, she had kept nothing down for four days. All the cardinal signs of Graves's disease were present: the eyes were prominent and staring, the thyroid was diffusely and markedly enlarged and a thrill was palpable over it, the hands were tremulous and sweaty, the pulse rate was 150 to the minute, and occasionally a beat was missed.

In view of the obvious gravity of her condition, Dr. Weston and I were doubtful if the risk of her removal to the General Hospital in Birmingham, ten miles away, should, properly, be faced, but the unsuitability of the home surroundings for insulin or any other treatment eventually decided us in favour of that course. On arrival at the hospital all her symptoms were exaggerated, in view of the extreme restlessness she was given morphine gr. 1/6 and hyoscine gr. 1/100 hypodermically without any effect. The morphine was repeated the next morning, but by the evening of the same day she was worse. Restlessness and delirium were marked, and auricular fibrillation was evident. A dose of quinidine was vomited, as was everything else, and her condition seemed desperate (I telephoned to Dr. Weston that evening to say I thought that she would die).

At this point I stopped all other treatment and ordered insulin (5 units) three times a day, together with frequent sweetened drinks. There had been no glycosuria, but she complained often of thirst and her mouth was parched. Within a few hours improvement was definite: she rapidly became quiet, the heart rhythm returned to normal, and after two days her condition ceased to cause any anxiety. A most striking feature was the fact that shortly after the first dose of 5 units of insulin she had some hours of natural sleep.

After reading Dr. Lawrence's paper on October 25th I felt that the dose of insulin might be increased, and 20 units were given before her midday meal, symptoms of hypoglycæmia ensued, which were relieved without difficulty by giving glucose by the mouth, the daily dose since has been 10 units, given in two equal parts. The general appearance of the patient has improved in an extraordinary way, the exophthalmos has almost entirely disappeared, the conjunctivæ still have an injected tinge, which was noticed for the first time two days after her admission, the heart rate is 120 and is regular; the thyroid is very much smaller, she eats a liberal diet and has obviously gained weight, there has been no vomiting since insulin treatment began and abdominal distress rapidly disappeared, mentally she is much calmer but is still inclined to be emotional, she sleeps well, and sat up for an hour without ill effect on the eighth day after her admission.

My object in writing this letter is to draw attention to the fact that a very acute case of Graves's disease strikingly improved in the unsatisfactory environment of a general hospital ward, which contained one or two noisy patients, after the administration of small doses of insulin, and, further, in view of the caution of the fourth paragraph of Dr Lawrence's summary, to point out that elaborate laboratory control was found, in this case at all events, to be superfluous.—I am, etc,

Birmingham, Oct 29th A P THOMSON

PORPHYRINURIA

SIR,—In his account of a case of haematoporphyria congenita, in the BRITISH MEDICAL JOURNAL of November 1st (p 803), Dr H T Ashby mentions the fact that most cases of porphyrinuria are the result of taking sulphonal or an allied drug for a considerable period. I should like to draw attention to veronal, one of these allied drugs, as a rare cause of porphyrinuria, hardly yet generally acknowledged.

In September, 1923, I saw a woman, aged 39, recovering from a very painful organic illness, who for more than two months had been having 5 grains of veronal almost every night as a hypnotic. Her urine for a considerable time had been deep red or red brown in colour, and free from haemoglobin and albumin. The colour was due to the presence of haematoporphyrin and disappeared gradually in the course of two weeks after the discontinuance of the veronal.

For a time the patient also suffered from paresis of the lower extremities (right knee-jerk absent), with pains in the calf muscles, possibly due to "haematoporphyrinuric polyneuritis."—I am, etc,

EPITHELIOMA OF THE SCROTUM IN COTTON-SPINNERS

SIR,—Dr Cochrane's letter on epithelioma of the scrotum (November 1st, p 835) is interesting. I have frequently seen something like a papulo-vesicular eczema—or as I should rather call it a papulo dermatitis—in the flexures of the scrotum and thigh when the two epidermic surfaces have been subjected to the influence of oil and collected perspiration for a long time.

Dr Leitch has clearly shown that a cancerous condition can be produced by a long continued enclosure of epithelial excretion, which I consider the most cancer producing substance known—in fact, the only thing which does produce cancer, in my opinion, is the product of dead and decaying epithelial cells. No one has ever pointed out anything else, amongst the multitude of causes and cures which have been put forward, that can outweigh this view.

Chimney-sweeps and others are not much given to frequent ablutions, so that the scrotal flexures suffer very much from neglect, often of long duration, and the deposits in the wrinkles of the scrotum are often not disturbed for years. Now, these conditions will certainly keep up a chronic irritation of the epidermis, which will some day result in epithelioma. Dr Cochrane has evidently caught this in the stage before malignancy has ensued, as the polymorphs described by Polland are, in my opinion, epithelial cells in the progress of their development. The dermatitis always yields to bathing with hot water and suitable applications unless the part has become malignant. Then I would say surgical intervention is necessary.

I can see no reason why spinners and chimney-sweep should exclusively possess this part for the expression of epithelioma. The only reason is the long neglect of conditions produced by the exposure to the exigencies of their occupation.—I am, etc,

Bolton Nov 3rd A W CRAWFORD, M B, C M

THE LEAGUE OF REMEMBRANCE

SIR,—On the eve of the sixth anniversary of Armistice Day it gives us great pleasure to testify to the activities of the League of Remembrance (1914-1919).

Having now had several years of experience of the work of the League, we are in a position to form an opinion of its usefulness. It confers practical benefits to all institutions connected with the health of the nation which care to seek its assistance. This opinion is based not only on an inspection of the work carried on at the League of Remembrance but also on our practical experience from the hospital point of view of its value in the work of the wards. Hospitals, infant welfare centres, and organizations of a similar kind have only to send materials and pattern and the League makes them up into the finished article required, without making any charge for its service.

We have personally inspected the workroom, the specially equipped department in which the surgical dressings are made receives our warmest commendation, and also the hygienic and aseptic principles which are exercised throughout the whole establishment. We can moreover testify to the promptitude, accuracy, and excellence with which the work is performed.

The League of Remembrance a continuation of the War Hospital Supply Depot movement is we believe the only institution of the kind in the world. It has proved of great service to the hospitals, and the number of appeals for help is continuously increasing. These appeals are straining its present resources to the utmost and we strongly recommend to public attention and support this organization, which has taken as an important part of its business of remembering, the relief of the sick and suffering.

All communications should be addressed to Mrs F H Gibson C B E Honorary General Manager League of Remembrance (1914-1919) 1, Marlborough Gate London, W 2.—We are, etc

ASSISTANTS IN GENERAL PRACTICE

SIR,—I was very pleased to read the correspondence in the JOURNAL on this subject. The poor remuneration received by assistants should certainly be made subject to inquiry by a responsible body, such as the British Medical Association, and a minimum should be fixed. It depends a good deal on the situation and style of practice but assistants are shamefully underpaid and overworked. The densely populated districts especially Stepney Bethnal Green, and Whitechapel, are the worst offenders in this respect. I know of one instance, not a hundred miles from Whitechapel where a male assistant is paid under £200 per annum and only gets half a day off per week.

The pay is inadequate enough but the hardest thing for a young assistant is to be deprived of liberty. During his student days he was used to hard work but he had ample time for sport and social intercourse when he enters into general practice as an assistant then he finds that he is suddenly cut off from all these. Nominally he is a member of his Branch of the British Medical Association but he never get an opportunity for attending meetings of the Branch or Division. His hopes of keeping up and improving his medical knowledge by attending a hospital for a few hours a week are doomed to disappointment for the reason he has not the leisure.

The surgery hours are far too long: two and a half hours in the morning and three to three and a half at night are unnecessary. There should not be any Sunday morning surgery. On Saturday the evening surgery should be in the afternoon between 3 and 5 o'clock in order to give the working men a chance to work a 1 p m on Saturday and can well attend in the afternoon. An assistant is on duty for twenty four hours daily. The weakness and the temptation for an assistant to become addicted to drink is that there is no alternative in front of him but [illegible] more fortunate than I am.—I am, etc,

F [illegible]

October 31st

CROWNER'S LAW

SIR,—Will you permit me through the courtesy of your columns to draw attention to a matter of very grave concern to the profession at large and at the same time to expose one more case of "official" interference and ineptitude? The official concerned is one of our non-medical coroners and the circumstances of his interference as detailed

In the course of my midwifery practice I had occasion to resort to forceps delivery on the supervention of signs of maternal and foetal distress *in a primipara*, aged 25 The baby was born *in a state of white asphyxia* at 4 30 p m on September 20th After an hour's artificial respiration I succeeded in resuscitating the child, which, however, died seventeen hours later I issued the usual death certificate of (1) obstructed labour, (2) asphyxia and convulsions (the "asphyxia" referred to "asphyxia neonatorum"), on the morning of September 22nd

On the morning of the 24th I received an insolent letter from the coroner telling me that "the cause of death as stated by you must have convinced you that this was a case which ought to be reported to the coroner," and formally calling upon me for *an explanation of my* conduct before "taking steps for the disinterment of the child and the holding of an inquest" It furthermore stated that "by your action the child has been buried before registration and without the registrar's authority or mine"

Accordingly I *made an appointment to interview* the coroner on the same afternoon, but found on arrival that he could not see me for "probably two hours" Shades of Chesterfield! At an interview on the following morning I learnt that the underlying cause of the commotion was the fact that the baby had been buried, but that the certificate of death, which the parents had in their possession some forty-eight hours, had not been delivered to the registrar until after the burial

I suspected that there was an attempt to place the neglect of the superintendent of the cemetery on my shoulders, and asked for a *precedent for the reporting of such deaths* I failed to learn of any legal enactment whereby one was bound to report such a death Incidentally, I pointed out that if the child had been stillborn there would have been *no occasion for this display of forensic acumen*

We agreed that I *should write a full report* of the case and forward it to the coroner I have never received any acknowledgement of my report—a fact which does not surprise me in view of my previous experience I have learnt since from many *of my friends in various parts of* the country that they invariably deal with such cases as I have done

Perhaps you would insert this letter as a warning to my professional brothers.—I am, etc,

NE OBLIVISCARIS

Obituary.

HENRY CARTER MACTIER, M B, B Ch,

Wolverhampton

WE have to record, with much regret, the death of Dr H C Mactier on October 28th Henry Carter Mactier was born in 1872, and was educated at Trinity College, Dublin, where he graduated M B, B Ch, B A O *in* 1894 He filled the post of house-surgeon at St Mark's Ophthalmic and Aural Hospital, Dublin, in 1894, and in the following year was house-surgeon in the Wolverhampton and Midland Counties Eye Infirmary In 1900 he was appointed honorary surgeon to the Wolverhampton and District Hospital for Women, and assistant surgeon to the Wolverhampton Eye Infirmary in 1903 later on becoming honorary surgeon His other appointments included those of honorary ophthalmic surgeon to the Royal Orphanage Wolverhampton, ophthalmic surgeon to the Bilston Education Committee, honorary surgeon to the Church Mission to the Deaf and Dumb in Staffordshire, and medical referee to various insurance societies In 1920 he was awarded the M B E for services in connexion with the war He was elected a member of the British Medical Association in 1897, and was a member of the Council from 1913 to 1921 He had been a representative of the South Staffordshire Division since 1910 and its honorary secretary since 1911 He was a member since 1912 of the Staffordshire Branch Council He was formerly a member of the Central Ethical, Medico-Legal, and Welsh Committees, and also of the Contract Practice, Maternity and Child Welfare, and Ministry of Pensions Subcommittees He was, *in short*, a fine representative of the kind of man who is always ready to undertake any kind of work for his profession, and who becomes the pivot *of that kind of work in his neighbourhood* Dr Mactier was also a member of the Midland Ophthalmological Society and had been a member of the Wolverhampton Borough Council He was the author of various papers in medical publications, including "The dangers of cocaine," "The effects of shock on chronic glaucoma," and "The indiscriminate use of atropine in eye diseases," which appeared in the BRITISH MEDICAL JOURNAL He was one of the founders of the Wolverhampton Rugby Football Club He also played cricket, and was an original member of the Newbridge Tennis Club

The funeral service on October 30th was attended by Dr T Ridley Bailey, representing the Council of the British Medical Association, and representatives of the South Staffordshire Division, the Eye Infirmary, and the Wolverhampton Insurance Committee, of which Dr Mactier had been re-elected chairman at the last annual meeting

---

IT was with much regret that the announcement of the unexpected death of Dr J L RENTOUL was received in the North of Ireland Dr Rentoul had had a mild attack of encephalitis lethargica in the early part of the year, and had *recovered and resumed* his work, although he *never quite regained his usual form* Lately severe abdominal and thoracic symptoms began to trouble him, which only very partially yielded to treatment, and it was decided to perform an exploratory laparotomy, although the great risk was *manifest, to obtain relief Unfortunately he succumbed in the attempt* John Lawrence Rentoul was a son of the Rev James Rentoul of Dromore, co Down He graduated M B Edin in 1900, and soon settled in Lisburn, co Antrim, where he acquired a large practice, but his bent was always towards the scientific side of the *profession* Soon after the war broke out he obtained a commission in the R A M C as temporary captain, and later was appointed bacteriologist to the hospital ship *Britannic*, and was serving on board when she was torpedoed in the Aegean Sea in 1916 *He was saved, and was put in* charge of a field laboratory in France, and remained in France till the war was over When he was demobilized he settled in Belfast as a clinical bacteriologist, and rapidly gained a large connexion *among the medical men and the public Latterly he devoted much time to tuberculosis*, and was testing a new serum treatment, which he was soon to put on the market, he had carried out many experiments and observations Dr Rentoul was a great favourite, and played a good game of golf, his reputation was extending rapidly, and his untimely loss is being deeply mourned by many, both in and out of the profession Much sympathy is felt for his widow, and his brother, the Rev Steele Rentoul of Glasgow

---

Dr J HORNE WILSON, who died recently, was the son of Councillor R G Wilson of Aberdeen, where he was born in 1876 After receiving his early education at the Grammar School and Gordon's College, he went to Marischal College, and graduated M B, Ch B Aberd *in* 1899 and M D with honours in 1903 He had served as house-physician to the Royal Hospital for Sick Children, Aberdeen, assistant to the Glasgow Maternity Hospital, and assistant physician at the Chief Tuberculin Dispensary, Chelsea He joined the R A M C in July, 1916, served with the 37th and 20 casualty clearing stations in France, being invalided on with the rank *of captain in* December, 1917 On returning to civil life he was appointed as a consultant to the Ministry of Pensions, but his continued ill health led to his retirement *in practice in* 1922, and he returned to Aberdeen He is survived by his widow, two sons, and a daughter

PROFESSOR AUGUSTE BROCA died on October 2nd, a few hours before the publication of his last work, *La Tuberculose chirurgicale*. He was born in 1859, the son of the late Professor Paul Broca, founder of the modern surgery of the brain. After a distinguished medical career, during which he specialized in the surgery of children, Auguste Broca entered the French Faculty of Medicine in 1913, first as professor of operative surgery, and later, as professor of topographical anatomy. After the war he was appointed to the chair of surgery of children and orthopædics. Professor Broca's more important works include *La chirurgie infantile*, issued in 1914, *La chirurgie de guerre et d'après guerre*, in 1921, and his posthumous publication on surgical tuberculosis.

DR. EUGÈNE ROCHARD, a well known Paris surgeon and member of the Académie de Médecine, has recently died, at the age of 71.

CORRECTION.—In the notice of Mr. R. Binyon's death published last week at page 837 the Christian name should be Edmund, not Thomas.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on October 31st the following medical degrees were conferred:

M.B., B.Ch.—D. E. Cuffey, A. G. Story.
M.B.—G. A. Thorn.

UNIVERSITY OF LONDON

SIR CUTHBERT WALLACE, K.C.M.G., C.B., has been elected Dean of the Faculty of Medicine.

A course of clinical lectures will be delivered by Dr. [illegible] at the Hospital Medical School on Tuesday, December 4th, at 4.15 p.m.

The first lecture will deal with recent light on the origin of syphilis; the second with the beginning of anatomical study; and the third with the scientific work of Robert Koch. The lectures are open to all medical students.

UNIVERSITY OF DURHAM

At a convocation held on October 29th the following medical degrees were conferred:

M.D. (Practitioners).—Ralph E. Drake Brockman.
M.B., B.S.—F. W. Marshall.

UNIVERSITY OF DUBLIN

THE Board of Trinity College has appointed Mr. James Edmond Hogan to be Lecturer in Dental Surgery and Pathology in the School of Physic, Dublin University, in the place of the late Dr. Arthur W. W. Baker.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

AN ordinary quarterly comitia of the Royal College of Physicians of London was held on October 30th, the chair being taken by the President, Sir Humphry Rolleston.

Membership

The following were admitted to the Membership, having passed the required examination:

Stanley Batchelor, *M.C.*, M.D. Lond., L.R.C.P.; Davis Evan Bedford, M.B. Lond., L.R.C.P.; Jyotish Chandra De, M.B. Calcutta, L.R.C.P.; William Devereux Forrest, M.P. Dunb., L.R.C.P.; Malcolm Kennedy, M.B. New Zealand; Anis Salama, L.R.C.P.; Kenneth James Livingstone Scott, M.D. New Zealand; Terence Watson Turner, L.R.C.P.

Licence

Licences to practise Physic were granted to the following 245 candidates who had passed the necessary examinations and had conformed to the bye laws and regulations:

C. H. Ackroyd, F. N. Adam, Iris I. G. Adams, C. Adamson, B. Addington, G. L. Alexander, A. J. Amor, S. M. Anger, on, T. F. Anderson, L. V. Angelo, H. Ankhorn, George the Patriarch, J. M. Bailey, H. C. J. Baker, G. W. Ambrose, L. J. Barford, Alison E. M. Barnaby, C. F. J. Baron, R. McG. Barron, S. A. Bearder, L. I. Beccle, A. E. Beith, P. C. Bennion, S. Perman, E. H. J. Berry, A. G. Perrick, H. E. Black, R. H. Bogason, A. J. S. L. Bond, W. H. Braddick, J. H. Broadhead, G. C. W. Brown, E. Buchler, G. H. Buncombe, F. C. Burge, M. Byrala, A. Canard, T. E. Cawthorne, F. Chandler, W. T. J. Chapman, F. W. Charman, K. T. Chaudhuri, W. J. F. Chidlow, Victor Cecil Churcher, S. Cleman, T. A. Clarke, F. E. Caxton, I. Cohen, W. R. F. Colli, W. S. C. Copeman, J. W. F. Cox, A. B. Cowley, B. W. Cross, B. Crowthwaite, W. I. Dagett, A. A. Dalby, A. F. C. Davey, D. Davies, D. J. Davies, E. W. P. Davies, Kathleen Davies, J. E. Davies, I. M. Deighton, G. W. S. de Jersey, P. H. Diemer, J. M. Dobie, W. A. Drake, C. S. Drarmer, J. Dresdon, W. A. D. Drummond, G. D. Dur, H. A. Dunlop, J. D. Durance, S. E. Durrans, D. E. Durward, H. C. Edmund, J. T. R. Edward, Josephine O. Ellen, J. P. Ellis, Marguerite Eman, H. G. English, A. J. Enzer, J. A. Evan, J. L. Evans, Sarah Evans, A. F. Ewan, W. G. Evans, N. J. Everard, S. Abdel Fadl, Fam, W. J. C. Fenton, F. E. Fox, D. Frost, G. A. Fulton, J. H. Gadsdon, H. C. Gage, J. A. Gallety, J. Gaughan, M. George, T. G. Gann, S. Gelb, Minnie Cohen, B. Green, F. G. Greenwood, C. E. Griffiths, J. I. Griffith, J. F. Hamilton, A. C. Hampson, C. L. Harding, H. E. Harparanes, Irma, J. H. Harper, V. E. Harris, Margaret I. Harford, W. A. Herbert, A. H. Hepworth, F. H. F. Hewer, J. G. Hume, W. F. Hunter, D. S. Hutton, H. V. * Under the Medical Act, 1886.

An alteration in By-law 194 was proposed permitting the election of women as Fellows of the College. This was passed for the first time. It will require to pass a second enactment subsequent to confirmation before becoming operative.

Dr. W. S. A. Griffith drew attention to a paragraph in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of October 4th, 1924, relating to an instruction by the American immigration authorities that persons who desire to emigrate from this country to the United States must be examined by medical practitioners who are members of the British Medical Association. After discussion in which Dr. I. A. Bolam, who was present, moved a resolution was passed drawing the attention of the President of the General Medical Council to the injustice the proposed arrangement would inflict on medical practitioners in this country who are not members of the Association and who would be precluded from giving medical certificates even to intending immigrants who were their own patients.

A report was received from Dr. Drewitt concerning the Chair of Physic Garden. It was directed that this should be considered on the minutes.

The President announced the award by the Royal College of Surgeons of the Jenks Scholarship for 1924 to Mr. Antonio J. C. Higham.

A report was received from the Committee of Management in regard to the institutions recognized for the courses of instruction for the several special diplomas.

Sir William Hale White was reappointed a member of the Committee of Management. Books and other gifts presented to the library during the past quarter were received and the thanks of the College were returned to the donors. After some formal College business had been transacted the President dissolved the comitia.

CORRECTION.—The announcement published last week (page 837) of Mr. Michael C. O'Malley's appointment as Professor of Surgery in the University College, Galway, and not Cork as previously stated, Professor C. Lambert Patterson, still holds the Professorship of Surgery at University College, Cork.

The Services

TEMPORARY DECORATION

THE Territorial Decoration has been conferred upon the following officer of the R.A.M.C.(T.A.): Majors F. W. B. Young, A. Walker, D.S.O., and G. B. Gill, and Captain E. B. Keen.

14TH STATIONARY HOSPITAL DINNER

THE fifth annual dinner of the medical officers of the 14th Stationary Hospital will be held on Friday, December 12th, at the Trocadero Restaurant, Piccadilly, at 7.15 for 7.30 p.m. Lieut.-Colonel J. T. Harper, C.B.E., will be in the chair. The privilege of the Loving Cup will be exercised. Dress: evening dress or lounge suit with miniature medals optional. The Honorary Secretaries are Lieut.-Colonel J. H. M. Perry and Dr. H. L. [illegible], 39, Devonshire Place, W.1.

V.A.D. TRAINING IN MILITARY HOSPITALS

THE War Office announces that arrangements have been made for a short course of annual training in military hospitals for a limited number of Voluntary Aid Detachment members. The instruction is to be held in certain [illegible] centres. The War Office will pay all [illegible] for the [illegible] of the training. The course will have a duration of [illegible] days, and will be open to members of Class A [illegible] at the discretion of the Commandant of the Hospital. Military Nursing Service.

Medico-Legal.

REX v HADWEN

MANSLAUGHTER CHARGE AT GLOUCESTER ASSIZES

THE trial of Dr W R Hadwen of Gloucester, on an indictment for manslaughter arising out of the death of a child whom he had attended, took place at Gloucester Assizes on October 27th, 28th, and 29th before Mr Justice Lush The counsel in the case were Mr C F Vachell, K C, and Mr StJohn G Micklethwait, on behalf of the Director of Public Prosecutions, and Sir E Marshall Hall, K C, and Mr A F Clements for the defence Dr Hadwen pleaded "Not guilty"

Case for the Prosecution

Mr VACHELL, in opening the case, said that Nellie Burnham, aged 10, died on August 10th last from diphtheria and pneumonia which followed it She was attended in her illness by Dr Hadwen, who, the prosecution alleged, failed, through gross inattention and lack of skill or knowledge, or both, to detect the disease from which the child was suffering and to administer the proper remedy Counsel then described the common symptoms of diphtheria and the general procedure of the medical profession in such cases, more particularly the taking of a swab from the patient's throat and the administration of antitoxin He went on to review at length the circumstances of the case and said that in spite of the highly suspicious symptoms Dr Hadwen never took a swab from the throat or administered antitoxin A fact to which, he understood, the defence attached importance was that two days before her death, while the mother was away from home, the child left her bed and went barefooted downstairs into the scullery to get a drink of water, but the evidence to be called with regard to the *post mortem* examination would show that the pneumonia was of the type which followed diphtheria, and not of the type which followed a chill

Mrs BURNHAM said that her daughter was taken ill on July 30th, and Dr Hadwen, her club doctor, was called in on August 1st He remarked that the case looked like scarlet fever He put two fingers in the girl's mouth and examined her throat, and examined her back and chest for any rash He prescribed a gargle of vinegar and water His examination occupied only three minutes The breath was very offensive, and there was a yellowish discharge, tinged with blood, from the nose She mentioned the foulness of the breath to the doctor on his second visit on August 4th, when he looked down the child's throat using his finger as before, but did not feel her pulse or take her temperature He came next on August 6th by which time she was weaker and the breath more offensive By this time the nose had a yellowish, spongy appearance like the throat The doctor's next visit was on August 9th, when, the child being weaker, she sent for him He looked down the throat felt the pulse and sounded the chest, but did not take the temperature He said that the throat was clearing nicely He stayed about five minutes At the previous visit he had prescribed a tonic He did not take a swab at any time The child vomited on August 8th On the evening of August 9th, the child being evidently worse there was a family consultation, and Dr Ellis summoned He took a swab of the throat and examined the child's chest and back, but she was then in a very grave state, and died on the early morning of the 10th

In cross-examination certain discrepancies in the evidence given by the witness compared with the evidence she gave at the coroner's court were pointed out, these related to the date on which she first suspected the case to be one of diphtheria In reply to further questions she said that she sent for Dr Ellis on the recommendation of her brother in law She knew nothing of an acrimonious dispute between Dr Ellis and Dr Hadwen in the public press She did not tell Dr Ellis that Dr Hadwen had seen the child earlier the case and was told what Dr Hadwen had done Dr Hadwen had been attending willing to give a death certificate, but she did not wish for one because being dissatisfied with Dr Hadwen's treatment, she wanted to have an inquest It had not occurred to her that it was not quite fair to Dr Hadwen not to tell him that the child was dead, so that he might be present at the *post mortem* examination She admitted that it was a rule of her society that in an emergency patients might send for the doctor at any time and that she did not send for Dr Hadwen after his visit on the 6th until the morning of the 9th, but she thought it was his place to come when the doctor came two days after the child had been down-stairs Re-examined she said that when Dr Ellis was called in three hours before the child died, it was the first time she had ever seen him He stayed two hours, he showed no ill feeling towards Dr Hadwen and said nothing about Dr Hadwen's treatment

Other witnesses—members of the family and neighbours—were called and gave similar evidence A brother in law of Mrs Burnham said that late on the evening before the child's death, he was at a family council telephoned Dr Hadwen to the effect that they were not satisfied with his treatment and had decided to call in another doctor Dr Hadwen replied that he had done his best Dr Ellis had been the witness's own doctor

Dr L S ELLIS said that when called to attend the child he found her seriously ill with a temperature of 102·5° and a pulse rate of 150 Her general condition was terrible When he came he was told that it was probably a case of diphtheria He noticed her very rapid breathing and at once thought of pneumonia He found the right lung solid and the left bronchitic In the throat he found membrane right across from tonsil to tonsil There was a discharge from one nostril—a greenish dirty discharge, just tinged with blood There might not be fluid in the chest, but on exploration found no fluid In his opinion the child was suffering from diphtheria and pneumonia He had no doubt whatever as to the diphtheria and before the result of the examination of the swab was available, even he notified it at once there was such obvious diphtheritic membrane He did not administer antitoxin because it was too late, the child was dying

In the course of a long cross-examination by Sir E Marshall Hall, Dr Ellis expressed the opinion that the diphtheria spread down into the lung, it was really all one disease The pneumonia in this case was unilateral according to the *post mortem* findings

Have you ever known a case of pneumonia, the sequel of diphtheria, which has been unilateral?

Witness No, bilateral either

Must it not be one or the other?

Witness I have never come across a case before—the cases go to the hospital It is a question for the pathologist

Was the pneumonia in this case lobar or lobular?

Witness When I auscultated that chest it was so like the whole thing was solid it might have been either

At a later stage in cross-examination counsel asked the witness whether, in August, 1923, he wrote to the editors of two London daily papers inviting them to send representatives to interview him with reference to Dr Hadwen, and whether in the course of his communication, which was not printed, he made a violent attack on Dr Hadwen and his professional status? Dr Ellis said there was certainly some discrepancy between Dr Hadwen's qualifications as given in the *Medical Register* and in a book printed locally There had been a very acrimonious correspondence between Dr Hadwen and a reporter called for information by the London newspapers and a reporter called upon him Dr Hadwen over the vaccination question I later he was asked to discuss matters with a view to the time this case arose there were some overtures with a view to making up the differences between the medical men in Gloucester

Dr W WASHBOURN, city bacteriologist, who made the *post mortem* examination, described his findings The back of the throat tonsils, soft palate, and larynx were intensely inflamed, almost black in one or two places An adherent patch of membrane at the back of the epiglottis was characteristic of diphtheria Both bronchial tubes were congested The right lung was solid throughout from inflammation The right bronchial tubes were filled with dense membrane, some of which was adherent and had evidently been formed *in situ* At the top of the bronchus was a piece of loose diphtheritic membrane, measuring about three inches by one inch In the pleural cavity there was a small quantity of fluid—about three ounces He could give an opinion with confidence as to the cause of death It was due to diphtheria and pneumonia He found the diphtheria bacillus present in the swab received on the day of the girl's death He received other swabs a day or two later from the medical officer of the isolation hospital He learned afterwards that these were taken from members of the family of the dead girl, and a playmate Two were negative, and two positive

In cross-examination the witness expressed the opinion that the condition of the right lung was that of lobar pneumonia of recent date—not more than two or three days old When he examined the swab he was not aware that the child from whom it had been taken was dead Although the Klebs-Loeffler bacillus was recognized by the great majority of the profession to be the specific bacillus of diphtheria it could be found also in some cases where there was no diphtheria He was aware just before starting the *post mortem* examination, that the child had been Dr Hadwen's patient, and that there was some charge of negligence against Dr Hadwen in his treatment of the case Dr Bell, deputy coroner (then acting coroner), was present at the examination not at his invitation but as a right, and he (witness) asked him whether Dr Hadwen was going to be present He thought the deputy coroner answered that Dr Hadwen had not been invited or that he was not coming After replying to further questions mainly about the symptoms of diphtheria and pneumonia, the witness said that the membrane he found *post mortem* was undoubtedly diphtheritic but he did not examine it microscopically he thought it so clear that it was not necessary to examine further Later the witness said that in this case, so far as he could judge the heart was healthy In a great many cases but by no means in all fatty degeneration would accompany acute diphtheria The duration of the pneumonia found *post mortem* would fit in although a "tight fit"—with the theory that the pneumonia was set up when the girl, two nights before her death got out of bed and went downstairs He did not think pneumonia caused by such a chill would have begun to manifest itself until from twelve to twenty four hours afterward but it was impossible to eliminate the circumstance as a cause of the pneumonia Nevertheless, in

felt sure that the diphtheria was a very large determining factor in the death of the child the right bronchial tubes were so extensively involved in membrane that this would have been likely to set up right sided pneumonia

Dr P B Berry M O H for Gloucester and medical superintendent of the city isolation hospital described the proper course to take when a doctor found the familiar symptoms of diphtheria present He spoke of members of the Burnham family who had been admitted to the isolation hospital during August suffering from diphtheria In cross-examination he admitted that antitoxin treatment was not always successful He considered the pneumonia in this case was secondary to the diphtheria The child died from diphtheria progressing through pneumonia to death

Dr E Graham of Gloucester said that he attended as her panel doctor an elder sister of Nellie Burnham on the day after the girl's death He took a swab of the throat and sent it to the medical officer of health In cross-examination he acknowledged himself a strong opponent of Dr Hadwen

Sir William Willcox in reply to Mr Vachell gave a description of diphtheria its origin and symptoms Vomiting might occur at the onset and again at a later stage when the disease became dangerous, it was a grave sign after the first or second day He outlined the prudent course for a medical man to take on finding a patient suffering from sore throat thickness of utterance offensive breath coloured discharge from the nose and drowsiness A swab should be taken and if there was to the naked eye a reasonable suspicion of diphtheria as evidenced by visible membrane or patches of exudation in the throat, then it would be his duty to give antitoxin without waiting for the result of bacteriological examination Diphtheria antitoxin had reduced the mortality from diphtheria from 30 or 40 per cent down to 10 per cent and under In 1895—two years before the antitoxin treatment was first used in this country—the mortality from diphtheria was 389 per million in England and Wales the figure in 1923 was 71 per million In his judgement the cause of this child's death was diphtheria and pneumonia Hearing the evidence he had no doubt the pneumonia was secondary to the diphtheria It was uncommon for this kind of pneumonia to be unilateral but he had seen it occur in diphtheria It was very difficult to say whether this was lobar or lobular but in view of the condition of the right bronchial tubes he thought this was a massive or very extensive bronchopneumonia In his opinion the child's journey downstairs would not cause the pneumonia such as was found in this case though it would of course be harmful at that stage of the disease and would subject the child to grave risk of heart failure In further evidence the witness said that Dr Ellis did quite the right thing in using the exploratory needle two hours before death It was difficult in children from clinical examination to be certain whether there was solid lung or fluid The risk in using the needle was infinitesimal In diphtheria the only treatment of any value was antitoxin treatment with general hygienic care Supposing the pneumonia was independent of the diphtheria the fact that the child was already suffering from neglected diphtheria would greatly diminish the resistance to the pneumonia however caused

Sir William Willcox in cross-examination said he saw quite a number of early cases of diphtheria in his hospital practice A long argument then ensued on the figure in the Registrar General's returns which counsel contended did not bear out the statement that diphtheria was now a less deadly disease than formerly Witness explained the meaning of the categories and the significance of the figures under each head and repeated that there had been a steady decline in the death rate from this disease in 1895 it was 313 per million of the population and now it was 71 Counsel next referred to statistics for 1922, which showed that 2 021 cases wrongly diagnosed as diphtheria had been admitted to the Metropolitan Asylum Board's hospitals and of these patients 77 had died Witness pointed out that these figures were for the London fever hospitals that the poorer districts of London were much overcrowded and that there was a tendency for practitioners to send cases to hospital when at all suspicious of diphtheria without waiting for the result of a swab lest other inmates of the crowded dwelling became infected These wrong diagnoses were cases of bad throats in which diphtheria was suspected but the bacteriological examination proved negative If these mistakes were not made the amount of diphtheria in London would be much greater Counsel next quoted from Sir George Newman's report for 1921 in which he referred to the increase in the figures for diphtheria due to the notification as diphtheria of cases of mild illness which seldom presented any definite clinical evidence and would not be regarded as cases of this disease apart from the fact of contact or the receipt of a positive report on throat swabs Witness said that this was true some doctors were over-cautious and notified diphtheria when the signs were by no means conclusive Counsel asked why the same argument should not apply to the Registrar General's returns Witness pointed out that these returns were based simply on the death certificate He was next cross-examined on Dr Washbourn's account of the *post mortem* finding In reply to the judge he gave a brief account of the nature and preparation of antitoxins and vaccines and was questioned as to a doctor's duty if he went counter to the opinion of the vast majority of his profession At the close of these questions his lordship addressing Sir E Marshall Hall said

You are faced with this difficulty Sir Edward that a person may hold a bona fide belief in some remedy without calling in a doctor at all but the courts have held that an honest belief that doctors do no good and that prayers alone have efficacy does not dispose of a charge of wilful neglect for not calling in a doctor The Legislature compels a parent to call in a doctor to his child

Counsel But no Legislature has yet compelled a doctor to inoculate with antidiphtheritic serum

His Lordship No but the difficulty still remains which I have pointed out.

Counsel next produced a work on differential diagnosis and asked whether in view of the diagram in that book the diagnosis between follicular tonsillitis and diphtheria might be very difficult Witness said that it might be impossible unless a swab was taken Asked whether there was not real danger in inoculation owing to anaphylaxis he replied that there might be a danger if the patient had previously been inoculated with serum but he had never in any fatal case through the use of antidiphtheritic serum Had a patient had had serum previously the record de was given with special precautions After further questions by counsel for the defence and a short re-examination by Mr Vachell his lordship asked Sir William Willcox a number of questions about the science of diphtheria antitoxin generally, and its efficacy when given early or late in the disease

Case for the Defence

Dr Hadwen giving evidence in his own behalf stated that his qualification — M D St Andrew L R C P L and M R C S Eng L M S S A He said he had practised for over thirty years He had had a fair amount of experience of diphtheria and about twenty five years ago was practising in Bristol when an epidemic of diphtheria occurred and most of the cases came under his care He had never administered antitoxin and all his cases had been successful Dr Hadwen then described his treatment of the dead child's brother Leonard who was suffering from septic tonsillitis He suspected diphtheria in Leonard's case and satisfied himself absolutely that no diphtheria was there He next attended another child of the same family who had the affection in a lighter degree When called first to Nellie he had been ill for two days He examined the throat and found a few raised patches on the right tonsil two on the left the throat was red He found no rash but there was a watery discharge from the nose He found a little harsh breathing in the chest pointing to light bronchial catarrh He ordered an expectorant mixture and a gargle of vinegar and Lotwater and gave a few general directions He left the child's pulse as a matter of course on every visit The pulse was quicker than normal and the temperature 100 His visit lasted roughly ten minutes The child was a poorly nourished rather stunted girl He saw no yellow blood-streaked discharge nor detected any offensive breath and the mother never said a word to him about such thing At his visits on August 4th and 6th the throat was better the bronchial catarrh had cleared up and the child was much better He intended to go again on the 6th but was too busy he was on his way there on the 9th when he was sent for He was thunderstruck at the change in the child and saw at once that her condition was serious The throat had cleared up nicely there was not a vestige of ulceration on the tonsils there was no membrane either upon the uvula or soft palate The breath sounds were deficient temperature 101° pulse 120 and he concluded pneumonia The mother never told him that the child had been downstairs He intended to call again that night but was informed by telephone that the family had called in another doctor He heard of the child's death about an hour before the inquest was held He had no notice of the *post mortem* examination He reaffirmed his opinion that the child had been suffering from ulcerative or septic tonsillitis and that she developed fatal lobar pneumonia

In cross-examination by Mr Vachell Dr Hadwen said that he doubted whether during the last three years he had had any case of diphtheria at all To administer antitoxin was against his views and his conscience he considered it a very dangerous remedy All these inoculations were based upon experiments on animals he objected to them on that ground but he objected to the antitoxin independently as a medical man He was taken through the usual symptoms of diphtheria and their relative importance and questioned by the judge on antitoxin at long discussion then ensued between his lordship counsel and witness on the Registrar General's statistics Dr Hadwen went on to say that he believed the bacillus to be the result of the disease not the cause and he saw no sense in taking a swab He discarded the whole germ theory of disease Asked by the judge what was his theory of the communication of disease he spoke of a chemical poison in the atmosphere The specific cause could not be discovered but unsanitary conditions affecting the atmosphere produced the disease Asked what would have been his treatment had he found diphtheria he said he would have put hot compresses around the throat painted the tonsils with glycerin three or four times a day and cautioned the mother to keep the child in a recumbent position He would of course have notified the case and in the circumstances would have advised the child's removal to the isolation hospital He contested Dr Washbourn's opinion that the membrane he found was diphtheritic

In re-examination by his counsel Dr Hadwen returned to the question of statistics He said that with the introduction of antitoxin diphtheria instead of being diagnosed in the old fashioned way became diagnosed by a very different method with the result that a great many common sore throats which would have got well in any circumstances were called diphtheria and this led to an apparent decrease of case mortality

Speeches of Counsel

Mr Vachell then addressed the jury at some length criticising the evidence which had been called on behalf of the prosecution He made a strong point of the fact that the only evidence other than Dr Hadwen's was medical Sir E Marshall Hall followed with a speech of many hours in support of the defence He brought attacks upon the character of the witnesses who had altered their evidence as to the sick child She had undergone a searching examination and quite a different thing in the post mortem after having in the meantime heard the medical evidence He described

it as most unfortunate that the second doctor called in by the family in this case was one who had been a most bitter opponent of Dr Hadwen in the press Dr Lilis never communicated the fact of the child's death to Dr Hadwen, and, what was still worse, the deputy coroner (Dr Bell) gave no notice of the *post mortem* examination to the man against whom, on the result of the examination, it was intended to prefer a charge Counsel hoped it would not be inferred that Dr Hadwen was the only medical man in England opposed to the administration of antitoxin He could not afford to keep eminent specialists at the court for three or four days

The Judge's Summing up

Mr Justice Lush, at the opening of his charge to the jury, said that the case was a serious one, with consequences to others than the immediate defendant

> It is a matter of great importance also to the public, and, I may say, to the medical profession, because while, on the one hand, persons are entitled to be, and must be, protected against criminal neglect or criminal misconduct on the part of a medical man, it would be deplorable—disastrous—if a medical man, following his profession according to the best of his judgement and acting honestly in the treatment of his patient, were to have hanging over his head a fear that if anything went wrong with his patient there might be a prosecution such as this

It was a case also which called for strong and clear proof on the part of the Crown The jury was not sitting merely to criticize Dr Hadwen's views It was not a case merely of saying whether he had or had not adopted views which a wise medical man should have adopted The charge against him was that he "did feloniously kill" the child, and it was necessary for the Crown to establish, not only that he neglected her, but that his neglect did actually cause her death Many cases had been tried in which a medical man, qualified or unqualified, had, in endeavouring to cure his patient, chosen to administer a dangerous drug or perform some operation, and if the drug was administered or the operation performed in a disgraceful and careless fashion, or with a disgraceful ignorance as to what the effect of the drug would be or as to the way in which the operation should have been performed, and the patient died, there was no difficulty in saying that the doctor or operator caused the death of the patient What was said in this case was very different It was that Dr Hadwen was so neglectful in his diagnosis and treatment that the child, whose life would have been saved if proper care had been taken, died through that neglect

> If a doctor is culpably negligent in his treatment of a patient, and the patient dies it is not enough for the Crown, in supporting an indictment of manslaughter, to prove that if the doctor had been careful the patient would have had a chance of getting successfully through the illness, the Crown must prove more than that, they must prove that in all human probability if care had been used the child would have recovered If the Crown have established to your reasonable satisfaction, first that the doctor did neglect the child, and secondly that in all human probability the child would have recovered if he had not neglected her, then, and then only, you will bring in a verdict of 'guilty"

His lordship considered that August 1st—the date on which Dr Hadwen first saw the patient—was the important date in the case The doctor had already attended the child's brother for a similar illness and the boy had recovered When he was called to see the child who subsequently died he found her not as bad as her brother had been and although he had called on the brother every day he did not call on the girl again until after three days Did the child on that first visit show such signs as would make an ordinary doctor suspect diphtheria or did she only show the signs of sore throat? Sir William Willcox had stated that unless antitoxin was given within six days from the commencement of the illness it was practically useless, and if Dr Hadwen had no reason on his first visit to suspect anything seriously wrong with the child's throat the child having already been ill for two days any neglect of the child from the second visit onwards would not make the withholding of the antitoxin a matter of very serious importance The Crown had to prove to the reasonable satisfaction of the jury that on the first visit the child showed signs of a serious malady which the doctor refused to consider

Next came the question of the pneumonia If the pneumonia was really a sequel of diphtheria then supposing the doctor to be responsible for the diphtheritic condition he was equally responsible for the pneumonic But if the pneumonia was brought about by an unfortunate act on the part of the child—going downstairs with bare feet on the tiled floor—which set up a chill and the pneumonia caused her death no one could say that neglect on the part of the doctor in the early days of the case had anything to do with causing the death of the child

> I come now to this question of neglect The law does not say that if a doctor is unfortunate enough to commit an error of judgement and the patient dies he is guilty of manslaughter The law does not cast upon anybody who is merely careless, and whose carelessness is the cause of the death of another, the responsibility of defending himself in the dock on this charge
>
> Unless the negligence of which a person is guilty is of so gross a character as to make one say of it that it is wicked negligence—not a careless but a wickedly careless thing to have done—the person concerned cannot be convicted of manslaughter There must be something evil in the negligence, something culpable, something criminal, before an indictment of manslaughter can be established You have got to ask yourselves, not whether Dr Hadwen failed to exercise that care which a doctor or anybody else ought to exercise, but whether he was guilty of what I have called culpable and wicked negligence If he was then the Crown have proved the first of the two things they have to prove, if he was not, the Crown have failed to prove even the first step

His lordship then reviewed the evidence of the mother and her friends, reminding the jury that the mother's evidence as to the bad condition of the child on the first visit was uncorroborated One could make all allowances for the mother, but he had not behaved in all respects quite in the way one would have expected her to behave She never told the doctor the very important circumstance of the child's visit to the kitchen and the jury might come to the conclusion that the mother's evidence was exaggerated as to the condition of the child on August 1st If the condition of the child was as Dr Hadwen said it was, his lordship could not conceive any ground for considering him guilty of criminal negligence in not taking a swab He next dealt with the evidence relating to the second and subsequent visits of the doctor and pointed out how the stories of the relatives and of the doctor conflicted

Coming to the medical evidence, his lordship said that if the child never had diphtheria then away went the case for the prosecution The child undoubtedly had pneumonia, if there was no diphtheria to cause the pneumonia it was probably caused by the chill It did not follow that if it was proved that the child had diphtheria the doctor was criminally neglectful, but here came the singular aspect of the case Dr Hadwen's views and mental attitude were different from those general in his profession The jury was not a tribunal to criticize his views

> But I think it is legitimate to say that it would be very unfortunate if any doctor were to close his eyes to the improvements in medical treatment which were accepted by the great majority of his profession, and to say, "I prefer the old-fashioned treatment, I do not believe in these others" After all, medical science is a very great science, and the medical profession a very great profession, and unless a doctor is going to wall himself off the discoveries made from time to time one is not likely to see that development of medical science which one hopes to see It does not follow from that, of course, that a man who will stick to his own views is guilty of culpable and wicked neglect A doctor, if properly qualified is allowed by law to follow and practise his profession in the way he accepts, and if a doctor does hold peculiar views—honestly holds them—and works them out and follows them, one cannot say that there is any culpable and wicked neglect, even though he is terribly and seriously mistaken But a doctor or anybody else—it is not for me to pass judgement on Dr Hadwen—may get his mind into such a state of prejudice and allow his judgement to be so blinded that really his position comes to this that he would rather sacrifice his patient than sacrifice his prejudice I do not say that is true of Dr Hadwen at all But there comes a stage when a man must be judged by what he does

Was the child (continued his lordship) suffering from diphtheria? The prosecution had got a very powerful body of evidence bearing on that question—the positive result of the swab the commencement of the membrane, the positive results found in the two other children Curiously enough, however there was a very strong difference of opinion between Sir William Willcox and Dr Washbourn Dr Washbourn's opinion—though it was only natural that in deference to Sir William Willcox's views, he should not hold it quite so strongly as at first—was that the pneumonia which caused the death was lobar pneumonia, and that would be an indication not of a secondary pneumonia brought on by diphtheria, but of a pneumonia caused by a chill Sir William Willcox took the opposite view, and stated that the pneumonia must have been lobular and a sequel of diphtheria It was for the Crown to prove that there was no reasonable doubt and if the doubt still remained he would warn the jury that they must be very careful before they convicted the defendant of manslaughter The neglect alleged against him was not in allowing the pneumonia to supervene, but in not discovering that there was diphtheria and taking proper steps His lordship added

> I cannot help saying that I agree with Sir E Marshall Hall that in a case like this, when this step, not often taken of bringing a charge against a practising doctor in respect to his treatment of a case was in contemplation, it is unfortunate that he was not allowed an opportunity of being present at that *post mortem* examination in order that he might see for himself what was shown to elucidate the case He was not there The microscopical examination of the membrane might have assisted him for aught one knows It is an unfortunate incident I do not advise you to attach too much importance to it but I do not think it right to pass over without expressing my agreement with Sir E Marshall Hall's statement

Verdict

The jury deliberated for twenty minutes On their return the foreman announced that they had agreed upon a verdict of *Not guilty*, an announcement which was received with loud applause in the crowded court Dr Hadwen was accordingly discharged

Medical News.

IN connexion with the forthcoming election of direct representatives to the General Medical Council, a meeting has been arranged by the Birmingham Branch of the British Medical Association to be held at the Medical Institute 154 Great Charles Street, Birmingham, on Monday November 10th at 4 15 p m , when Dr J A Macdonald and Sir Jenner Verrall will address their prospective constituents At a meeting convened by the Lancashire and Cheshire Branch to be held at the Brasenose Club 94, Mosley Street, Manchester, on Tuesday, November 11th at 4 15 p m , Dr R A Lolam and Dr H B Brackenbury will speak The election addresses of the four British Medical Association candidates was published in the SUPPLEMENT of last week (p 161), together with the first list of supporters, a further list of supporters appears in the SUPPLEMENT this week

THE next Chadwick public lecture will be on "The rat menace—its true significance and how it can be minimized by Mr T Mark Hovell, F R C S , in the Barnes Hall, Royal Society of Medicine, 1, Wimpole Street, on Monday, November 10th, at 8 p m

DURING November a course in venereal diseases will be held at the London School of Dermatology (St John's Hospital) At St Mark's Hospital a two weeks course in proctology will be held from November 10th to 22nd, and at the Chelsea Hospital for Women a course from Friday November 21st to December 6th At the Royal Waterloo Hospital a course in medicine, surgery, gynaecology and children's diseases will be given from November 24th to December 12th Syllabuses of the courses may be obtained from the Secretary of the Fellowship of Medicine, at No 1 Wimpole Street, W 1

UNDER the Workmen's Compensation Act a medical board will probably be appointed shortly to undertake the examinations required by the Refractories Industries (Silicosis) Scheme, and in our advertisement columns to-day there appears an announcement about the two whole time medical officers who will be required The board will have its centre at Sheffield, and the senior medical officer appointed must have had not less than ten years practice in the diagnosis of respiratory diseases, with special experience of silicosis It is intended to imitate as far as possible the South African scheme and provide opportunities for systematic scientific research

AT the quarterly meeting of the Medico Psychological Association of Great Britain and Ireland, to be held at 11 Chandos Street W 1, on November 20th, at 2 30 p m Dr G de M Pudolf will read a paper entitled "Malarial treatment of general paralysis some psychological and physical observations

THE new home for nurses of the Royal Northern Hospital, Holloway, was opened by Princess Louise, Duchess of Argyll on October 30th The new building affording accommodation for 58 nurses is part of a scheme to provide for 120 nurses, with administrative offices, classrooms, and dining rooms

THE post graduate lecture at the Royal Dental Hospital of London by Mr D P Gabell announced for November 19th, has been postponed until January 30th, 1925

THE meeting of the Royal Sanitary Institute at 90 Buckingham Palace Road, S W 1, on Tuesday, November 18th at 6 p m , will be devoted to a discussion on the economic value of the healthy infant and the New Zealand welfare work to the State

AT a meeting of the Pathological Section of the Liverpool Medical Institution on October 30th Professor J M Beattie read a paper on the carriage of infection by rats with special reference to foot and mouth disease From the lymphatic glands of an animal not considered by the Ministry of Agriculture to be infected he had obtained a virus which by inoculation caused lesions of the feet and mouth in rats, and was transferable from one rat to another In the routine examination to protect the community from plague 55 rats out of 279 examined were found to have lesions of the feet and mouth similar to those produced by this virus and the frequency varied with the outbreaks of foot and mouth disease in the city A map shown demonstrated clearly that these diseased rats were mostly obtained from sewers leading from the abattoirs, farms, and butchers shops where the disease was known to have occurred Other rats from the infected areas showed similar lesions, even gelatinous degeneration of the lungs

SIR GEORGE WILLS is making a gift of £60 000 to the Bristol General Hospital, of which he is president, for providing an additional nurses home and a new out patient and casualty department

THE annual Armistice Dinner of the Belfast University Services Club will be held in Thompson's Restaurant Belfast on Tuesday November 11th, at 7 15 p m At 11 a m on Armistice Day wreaths in memory of fallen Queen's men will be placed at the Cenotaph Whitehall, and at the War Memorial in the University grounds

THE Royal Anthropological Institute announces that the Huxley Memorial Lecture will be delivered this year on Tuesday November 25th at 8 30 p m in the rooms of the Royal Society, Burlington House Piccadilly, by Professor Pere Verneau, who has chosen as his subject La Race de Neanderthal et la Race de Grimaldi leur role dans l Humanite

A MEMORIAL to Italian doctors who fell in the war was unveiled at Florence on November 1st in the presence of the King and Queen of Italy

THE November issue of the *Traveller in France*, an official publication issued by the Office Français du Tourisme (55, Haymarket, S W 1) gives an account of the mountain passes in the Alps considered as winter health resorts Brief descriptions are given of Vernet les Bains, Corsica, and Grenoble

THE late Sir Frederick Needham, M D , formerly a Commissioner of the Board of Control has left estate of the gross value of £29 381 with net personalty £28 905

THE medical school of Pondicherry in French India which was founded in 1823 and reorganized in 1863, has granted nineteen medical diplomas during the last ten years The average yearly number of medical students during this period has been 14 5

WE have received a well illustrated pamphlet on open air schools in New Zealand—published in Christchurch—by I G MacInnes, Dr N B Philipps assisting in its preparation The measures for dealing with adverse winds are shown, and an account is given of the progress of this movement since 1904 As the author states "the open air school is the logical sequel to the Plunket scheme

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS *forwarded for publication are understood to be offered to the* BRITISH MEDICAL JOURNAL *alone unless the contrary be stated* Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager 429 Strand W C 2 on receipt of proof

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager 429 Strand London W C 2 Attention to this request will avoid delay Communications with reference to editorial business should be addressed to the Editor BRITISH MEDICAL JOURNAL 429 Strand W C 2

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication

Communications intended for the current issue should reach the office not later than first post on Monday or at latest by the first post on Tuesday morning

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange) The telegraphic addresses are

QUERIES AND ANSWERS

EPILEPTOID FIT

"H C B " asks for suggestions for the treatment of epileptoid attacks in a little girl aged 9 The attacks resemble those of grand mal and sometimes those of petit mal they began at 4 months old A first and typical attack occurred every two or three weeks but the attacks much more frequent—about every two days The bromide bromural belladonna luminal diallace in and glandulare acetate have been tried but our correspondent could not ascertain whether any one of them had an real effect she is now controlled them when as an infant she had whooping cough threatened with status epilepticus She is backward, but "mentally", he physical condition perfect

Treatment of Asthma

"J G G" asks for suggestions for the treatment of a lady aged 60, who has suffered from asthma for five years Her present attack has lasted over six months There is no history of heredity or neurosis, and there is no naso pharyngeal abnormality Potassium iodide over prolonged periods, adrenaline, morphine, lobelia, stramonium, and the exclusion of cats, feathers, etc , have all proved failures

Liquid Paraffin and Cancer

Dr S Watson Smith (Bournemouth) writes In your issue of November 1st, p 840 "B K" asks whether those who see many cases of malignant disease of the alimentary tract suspect the taking of liquid paraffin as a cause Shortly after liquid paraffin came into more general use, the late Dr Allan Jamieson of Edinburgh, in a letter to the British Medical Journal, issued a warning and a reminder of the fact that paraffin workers were, on account of their employment, particularly liable to cancer An enormous amount of paraffin, solid as well as liquid, must be consumed daily in this country, and chiefly by those who are past the age of full development One cannot easily avoid ordering it when so many preparations and so called "foods" have paraffin *entering into their composition* Even with a guarantee it is impossible to be absolutely certain of purity or of the absence of all impurity Paraffin used in ointments and pastes seems to harm few skins, if it cannot be tolerated, another vehicle is substituted It has however, to be remembered that ointments containing paraffins have only an occasional use for any particular patient and for seldom longer than days or weeks at a time *Taken internally for* months or years, as it commonly is nowadays, may make all the difference in risk, and the few who have the misfortune not to tolerate paraffin well may run a greater risk of future malignant trouble Within the past few years I have seen three cases of a dry form of dermatitis of both hands in motor car mechanics, apparently caused by handling petrol and lubricants It is understood that *paraffin causes cancer because of impurities in it* If little or no absorption takes place in the intestine, the paraffin being supposed to be inert such impurities, if they exist, may yet quite easily exert their action anywhere in the body by becoming assimilated The risk attending the taking of paraffin in any form has for some years prevented my prescribing it except in special cases If the Imperial Cancer Research Fund could give some guidance or advice in the matter of the internal use of paraffin, I for one should be grateful

Income Tax

Partnership Assessment

"Delta" inquires whether the inspector of taxes is justified in refusing to issue separate notices of assessment to two partners

*** The answer is "Yes" In 1907 the system of making separate assessments on partners was abolished by statute, and since then the assessment is required to be made in one sum on the firm At the same time it is the practice—so far as we know, without exception—for the inspector of taxes to give any reasonable assistance he can to the members of the firm in the task of dividing the firm's liability correctly between the partners If the inspector absolutely refuses to amplify the brief partnership statement he has given "Delta" might send the statement to us with such further information on the point as he may be able to give

Change in Appointment

"H A H" was appointed to a lectureship at £750 per annum as from December 12th 1921, and has been assessed to pay £61 10s income tax for the period to April 5th 1922 Is this correct? He was previously assessed in another district at the rate of £800 per annum for the year 1921, up to November of that year

*** The sum of £61 10s is correct provided that "H A H" has had all his personal allowances from the assessment on his *previous earnings*, we gather from the inspector's letter that this is the case The only possibility of any adjustment being due to "H A H" is that the previous assessment should be for the period April 5th (and not January 1st) 1921, to the date in November as from which his former appointment terminated "H A H" might find it advisable to obtain particulars from the inspector who dealt with that liability setting out exactly how the duty he paid for 1921-22 in that district was calculated

LETTERS, NOTES ETC

Obstinate Nasal Catarrh in an Infant

Dr Fred Nash lecturer in osteology University of Sheffield in reply to "G L" (October 18th p 749), writes that the nasal catarrh is probably kept up by the frequent insertion of cotton wool soaked in various things in to the nose, with a mistaken idea of cleansing it All such applications should be stopped and sneezing induced The child will clear the nose by its own efforts and fresh supplies of the bactericidal mucus will be able to act when the *debris of old mucus is* removed by the sneezing To induce sneezing manipulation should be tried first gentle massage of the forehead particularly over the distribution area of the supraorbital nerve with the hand or with hair brush Another way is tickling the orifice with dry *cotton wool taking* care not to poke any up the nose If these manipulations fail success can be induced by gently touching the septum of the nose with a probe covered with a few grains of powdered Castile soap, other substances with the same effect are Hudson's scap ginger, or pepper Only a few grains are required for a baby When the sneeze has occurred the nose should be stroked gently downwards, as if "milking" it

Rapid Sterilization of Hypodermic Syringe and Needle

Dr W Johnson Smith (Bournemouth West), who has recently had occasion to note several instances of bad arms, sends the following simple method of sterilizing hypodermic syringes and needles Place them in an ordinary test tube one third full of water and heat to boiling point a disc of cork as big as a sixpence placed in the bottom of the tube will prevent the point of needle from injury

Cancer in African Natives

Writing with regard to Dr Old's letter published on October 11th (p 689) Dr Charles F Harford (London) refers to the suggestion that malignant disease may be due to bad auto suggestion, and that suggestion and auto suggestion may be employed in their treatment Dr Harford thinks the clue should be followed up and that the leaders in cancer research should widen the scope of their inquiries and make use of the light which may come through modern psychology He adds The psychological factor in malignant disease has been considered by many and in June, 1923, I had some correspondence on this subject with Dr Archibald Leitch In a letter which he was good enough to write to me on June 2nd of *that year he gave various reasons* for doubting the importance of mental stress in connexion with cancer and in the course of his argument he wrote as follows "But above all certain animal species which do not impress us as having mental processes subject to the influence of emotions, contract malignant disease as commonly as and in some cases more commonly than, human beings The *tame mouse*, as you know, kept in laboratories, *well fed, well cared for*, and removed from the vicissitudes *of life that the wild mouse* has to face develops cancer even more *frequently than does the human* being Dogs, cats, horses, and even placid cows develop cancer Where does the mental stress come in?" Needless to say I have given much thought to this interesting reply and I have been led to connect this statement about cancer in animals with *the knowledge* we have about primitive races The animals referred to are domestic animals, and in particular the tame mouse is "*removed from the vicissitudes* of life that the wild mouse has to face" This means that the life of liberty with its sporting chances has been exchanged for the *enforced confinement* of the laboratory Is there not a close analogy between these and the primitive races who have too quickly exchanged the habits of generations for the artificial life of a *civilization* strictly European in pattern? In each case there has been a violent dislocation of instinctive forces with greater liability to interference even with physical processes

Dental Skiagrams

Sir John O'Conor (Buenos Aires) writes As complement to my note published in the British Medical Journal, August 16th (p 299) I should be obliged if you could allow me to state that I have every hope that within a short period, as confirmatory diagnostic routine, we shall see in every well appointed clinic radiological general examination of the teeth linked with exhaustive logical, etc , examination of the blood

A Surgical Sling

Dr J M Dewar (Edinburgh) informs us that a patient of his, a partially disabled ex soldier, has recently patented an adjustment for carrying surgical slings which eliminates strain on the wearer's neck It is in the form of a waistbelt *fitted with* adjustable brace straps (each bearing a flat hook), which fit into slides on an ordinary sling The weight is thus hung from the shoulders and equally distributed When adjusted it remains firm and there is no discomfort, such as is caused by a slipping knot The adjustment has been worn *for* seven months with comfort to the wearer, who formerly suffered pain and inconvenience from pressure on the neck

A Death Certification Problem

Dr H L Pearson (Newcastle) writes I recently attended a young primipara in a premature labour—about the eighth month She gave birth to a *live child*, which, however, lived for only fifteen minutes The features were Mongolian in type the right forearm was deformed, and *there was only one bone* of *limb arising from* the centre of the pelvis The child resembled a "Punch and Judy" doll mounted on a stick *The most* interesting *feature* was the entire absence of anus or external genitalia As the child had had a distinct separate existence a certificate of *death had to be supplied*, raising the difficult question—how to fill up the form

Correction

In the report of the scientific meeting of the Oxford Division published *last week at page* 815, for "fourteen" (col 2, fourth line from top) read "four"

Vacancies

Notifications of offices vacant in universities, medical colleges, and of acting resident and other appointments it has been will be found at pages 40, 41 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43

A short summary of vacan posts notified in the advertisement columns appears in the *Supplement* at page 179

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

350 Total Heart-block due to Gumma

G J VAN DEN BOVENKAMP (*Nederl Tijdschr v Geneesk*, September 20th 1924 p 1502) states that total heart block is the condition in which no impulses pass from the sinus to the ventricle The latter then contracts regularly by itself with a frequency of about thirty beats a minute while the sinus contracts with much greater frequency The cause of the condition is to be found either in arterio sclerosis of the vessels supplying the bundle of His or in a gumma affecting the bundle It is obvious that a cure is impossible in arterio sclerosis, whereas in a case of gumma recovery may take place Van Bovenkamp records a case in a man, aged 60, who presented a systolic murmur at the apex, a pulse of 33, a systolic blood pressure of 225, and a diastolic pressure of 100 mm Hg The patient complained of shortness of breath was pale, and slightly cyanosed Signs of arterio sclerosis were present in the peripheral vessels, as was to be expected in a man of his age Although there was no history or evidence of syphilis, specific treatment by intramuscular injections of mercury perchloride and potassium iodide internally was instituted, with the result that after a period of partial heart block the pulse rose to 90 and the blood pressure fell to 170 systolic and 95 diastolic, and all the other symptoms disappeared It is not unlikely that the gumma was situated in the bundle of His as it could not have disappeared without leaving a trace of its presence, but it is more probable that its close juxtaposition caused pressure on the bundle or interfered with its blood supply

351 Asthma and other Anaphylactic Idiosyncrasies

K BAAGÖE (*Ugeskrift for Laeger* July 31st, 1924 p 577) publishes investigations which suggest that several apparently independent idiosyncrasies may depend on a common factor In support of this thesis he refers to the case of a 9 year old boy who suffered from attacks of asthma and who also showed a marked idiosyncrasy to eggs As soon as he ate a particle of egg he suffered from nausea and vomiting but on these occasions he never suffered from an attack of asthma To overcome his idiosyncrasy to eggs he was given egg powder in gelatin capsules the amount being gradually increased from a few milligrams to 5 grams All went well till one day when a capsule of egg powder having been broken he inhaled a little in the act of swallowing the capsule A few minutes later his lips and mouth became very much swollen he developed a violent coryza his voice became hoarse and piping, and an attack of asthma set in The author concludes that the boy's idiosyncrasy to eggs was not due to their absorption by the stomach but to nausea caused by oedema of the fauces provoked by eggs in the act of swallowing The sequence of events—first oedema of the mouth with a coryza, then hoarseness, and finally an attack of asthma—suggested that the whole attack including the asthma, was due to urticaria of the respiratory tract rapidly spreading from the mouth and nose to the bronchioles

352. Incidence of Tuberculosis among Nurses and Ward Maids

O SCHEEL (*Tidsskrift f d Norske Laegeforening* August 1st, 1924 p 709) has investigated the incidence of tuberculous diseases among the 2 913 nurses and 1 411 ward maids employed in the communal hospitals of Christiania in the six year period 1918 to 1923 There were 63 cases among the nurses (2 16 per cent) and 23 cases among the ward maids (1 63 per cent) The pleurisies alone were almost as numerous as all the other tuberculous diseases put together and it was significant that of the 27 cases of pleurisy among the nurses as many as 15 occurred during the first year of service There were 8 cases in the second year 3 in the third year 1 in the fourth year, and none in the later years of hospital service The author suggests that these figures may indicate a state of affairs requiring reform A young probationer who may have come from the country and be still negative to von Pirquet's test is given daily hard work of body and mind for nine hours or more and is exposed to infection if stationed in a tuberculosis ward The author's remedy is that every probationer should be tested with the von Pirquet tuberculin reaction and if no reaction to it she should be kept out of contact with tuberculous patients, at any rate for the first year

353 The Contagiousness of Lethargic Encephalitis

G STIEFLER (*Wien Klin Woch*, August 28th 1924 p 850) has seen twelve examples of the transmission of the contagion of lethargic encephalitis In six infection was probably caused by direct contact including three cases in which there was a familial or house infection In five cases there was probably indirect contagion through a healthy third person, and in one case it was uncertain whether the contagion occurred directly or indirectly The incubation period in the six cases of direct contagion ranged between six and twenty one days Of the infecting cases eight were in the acute stage and four were in the late stage, including three in which an acute exacerbation occurred Those who deny the possibility of transmission of lethargic encephalitis may be reminded of the epidemiology of acute poliomyelitis, which for a long time was not regarded as contagious until it was at last proved to be so, mainly owing to the investigations of Ivar Wickman In view of the contagiousness of lethargic encephalitis isolation should be carried out as early as possible, both in acute cases and in chronic cases during a relapse

Surgery.

354 Acute Osteomyelitis of the Ilium in Childhood

P BUONSANTI (*Arch Ital di Chirurg* September 1924 p 1) publishes four cases of this rare condition—how rare is shown by the fact that out of 170 cases of osteomyelitis seen by him in the last fourteen years these four are the only iliac cases he has encountered. Full details with skiagrams are given of three of the cases, and a bibliography of some twenty references is appended As in other cases of osteomyelitis the *Staphylococcus aureus* is usually the causative agent, and in half the author's cases there was a history of previous trauma Diagnosis is very difficult owing to the deep-seated position of the lesion, and radiography apart from showing a definite periosteal reaction does not help much in distinguishing it from new growth Owing to the ease with which metastatic visceral lesions are set up the disease is of marked gravity and the mortality high Early treatment of the diseased bone is essential and when the sequestrum is immersed in pus it should be removed In the author's cases the osteomyelitis started primarily in the ilium Grouping the statistics of 1 469 cases of osteomyelitis only 23 were localized in the ilium Osteomyelitis may be called a 'furunculosis of bone since the staphylococcus plays such a prominent part in its causation In the fourth case the boy suffered from cutaneous furunculosis which might have been the starting point of his osteomyelitis The internal surface of the ilium is more vulnerable to osteomyelitis than the external, the pelvic organs do not seem to be affected as a rule in osteomyelitis of the ilium and in metastasis He concludes that vaccine therapy has not given particularly good results in these severe cases, but should be tried.

355 Tumours of the Carotid Gland

A BIPLEX (*Deut Zeit f Chir* July 1924 p 384) has collected 90 cases of tumour of the carotid gland including one of his own and places them in two groups In the first group the tumours are benign in character and more or less closely resemble the normal carotid gland in structure It is uncertain, however whether these growths are merely hyperplasia or examples of true blastoma and for this reason stroma appears to be the most suitable term to apply to them The second group consists of malignant growths which invade the surrounding tissues Regional metastases are rare and distant metastases have hitherto not been observed Severe symptoms are exceptional and in many cases the patient seeks advice on cosmetic grounds The diagnosis is difficult and can hardly ever be made except by exclusion It is important however to remember the possibility of these tumours owing to the prognosis and indications for operation The treatment is purely surgical Operation however should only be undertaken when the tumour is small or the pain is very severe and there is suspicion of malignancy Only about 13 per cent of those operated on recover this unfavourable result being largely due to following circumstances The common internal carotid artery is removed in 70 per cent of all cases of which a quarter develop hemiplegia which in about 50 per cent In 20 per cent the vagus is resected half the cases developing deglutition bronchopneumonia The other deaths are due

an embolism, sepsis following operation, haemorrhage from slipping of a ligature, and intercurrent disease Apart from hemiplegia and shock, the most frequent sequelae of the operation are narrowing of the pupils, paralysis of the vocal cords, hoarseness, and difficulty in swallowing Birman's patient was a man, aged 54, who had noticed a swelling on the right side of the neck for five years without its having caused any symptoms It was only within the last few weeks before consulting Birman that there had been a rapid increase in its size, with a dragging sensation on the right side of the neck The patient had never been hoarse, and only wished to have the tumour removed for cosmetic reasons The growth, which was about the size of a hen's egg, was removed after ligature of the right internal carotid Two days later left hemiplegia developed When seen three months later the patient was able to walk without support, but had only a little movement in the left arm and complained of occasional epileptiform attacks Histological examination of the tumour showed that it was a hyperplasia of the carotid gland

353 Snap-finger and Polyarthritis

J HELWEG (*Ugeskrift f Laeger*, July 17th, 1924, p 546) notes that, while in the healthy snap finger seems to occur only in connexion with prolonged trauma inflicted by such acts as gripping the handle bars of a motor bicycle too firmly, this condition may arise almost spontaneously in the subjects of polyarthritis, whose tissues appear to be peculiarly vulnerable in this respect Among 413 cases of polyarthritis treated at the author's hospital in the period 1918–23, there were 21 with a record of snap finger Since he began to study this condition intensively the author has found it often in the subjects of polyarthritis, 11 out of 23 cases seen since January 1st, 1924, showing one or more snap fingers In many cases of polyarthritis it was the snap finger, rather than the articular changes in the fingers, which caused pain, interfered with the usefulness of the hands, and was responsible for the swelling As in healthy persons, the subjects of polyarthritis develop snap finger most readily when prolonged pressure on the palm of the hand is produced by such acts as resting heavily on a stick If this condition is neglected, a stage may be reached when the finger ceases to snap because the fibrous infiltration of the tendon and its sheath has become so great that movements of one in relation to the other are no longer possible This stage is not reached simultaneously by all the snapping fingers, some continuing to snap after others have become silent Early in the disease the most troublesome symptom is the pain felt at rest as well as on movement, later, the purely mechanical limitation of the finger movements gives more trouble The author insists on the importance of prophylaxis—that is, avoiding acts calculated to injure the hands of the subjects of polyarthritis Such prophylaxis may also prevent the further development of the disease, but, as one of the author's cases shows, transferring a walking stick from one hand to the other, because the fingers of the first hand have begun to snap, may merely mean provoking the disease in the other hand Massage is usually effective in banishing pain and tenderness, even in chronic cases in which great infiltration of the tissues has occurred This treatment also increases the range of movement of the fingers The author refers to operative treatment in no flattering terms.

Therapeutics.

357 Metallic Mercury Suspensions in Treatment

H N COLE, J G HUTTON, J RAUSCHKOLB, and T SOLLMANN (*Journ Amer Med Assoc*, August 23rd, 1924, p 593) discuss in considerable detail the therapeutic results of the intravenous and intramuscular injections of metallic mercury suspensions, with especial reference to the use of mercodel," "uration of mercury with glucose in the LETTEfive They found that intravenous produced a rapid disappearance

OBSTINATE NASAL Cas of primary syphilis, prompt

Dr IAN MARSH lecturer in ossions, and improvement in the n reply to G L (October 18th observable within a day or catarrh is probably kept up by the lapses occurred unless the wool soaked in various things into in six injections being nea of cleansing it All such applica e amount of mercury and sneezing induce? The child will c ut was much greater efforts and fresh supplies of the bacteria cts on the kidneys to act when the debris of old mucus is rem to induce sneezing manipulation should seemed to be some mas age of the forehead particularly over the nto severe and of the supraorbital nerve with the hand or w the repeated Another way is tickling the orifice with dry cotton y reactions care no to pole any up the nose If these manipul similar sneezing can be induced by gently touching the sep nt They

therefore consider the risks too great to justify at present the therapeutic use of this suspension They give details of the treatment of 23 cases to illustrate their contentions.

358. Treatment of Epidemic Encephalitis with Trypaflavine.

BUSS and PELTZER (*Deut med Woch*, July 25th, 1924, p 1014) confirm an earlier publication by Buss in which he showed that intravenous injections of trypaflavine were remarkably effective in the early stage of epidemic encephalitis The authors' present paper includes a detailed record of sixteen cases, many of them severe, in which trypaflavine was given with more or less good results even when, as happened in some cases, the disease had lasted for some time before the treatment was instituted The usual dose of trypaflavine was from 5 to 15 grams injected every day, in one case, which terminated in recovery, as many as forty four injections were given over a period of three months, a total of 400 c cm of the 0 5 per cent solution of the drug being given in this period This was the only case in which the injections seemed to provoke bladder symptoms Though in none of the published cases was the daily dose of trypaflavine more than 20 grams, the authors recommend doses of 20 to 60 grams a day by intravenous injection They suggest that timid dosage comparatively late in the disease may well be responsible for the lack of faith in the efficacy of trypaflavine in this disease

359 The Action of Digitalis

H VAQUEZ (*Arch Mal du Coeur, des Vaisseaux et du Sang*, October, 1924, p 609) reviews modern theories of the action of digitalis, the indications for its use, and the method of prescribing it He remarks that the collection of digitalis leaves is particularly unsatisfactory, many specimens of the drug are almost inert owing to improper methods of collecting and drying the leaves, which contain oxydases capable of producing profound chemical changes in the glucosides should fermentation occur He finds "digitaline cristallisée" (Nativelle, 1868) still the most reliable preparation Vaquez advances several objections to standardization of the infusion and tincture by animal experiment, and asserts that advances in our knowledge of the action of digitalis have been due to clinical observation rather than to physiology He maintains that Lauder Brunton's description of the phases of the action of large doses of digitalis still holds good, except that he was in error in stating that the drug is diuretic even in health Vaquez points out that digitalis acts directly on the myocardium, and when this is damaged digitalis may interfere with the transmission of the impulse from auricle to ventricle, causing pulsus bigeminus and extra systoles by increasing the muscular irritability When this is very marked it may indicate disease of the myocardium or of the bundle of His and necessitate a grave prognosis Vaquez objects to the term "cardiac tonic" as applied to digitalis, and observes that Harris has described three phases in its action (1) Diastole and systole are both prolonged, without augmentation of systolic contraction or of the volume of blood The heart is "slowed," probably as a result of action on the sinus, this is of small value in relieving the circulation (2) Systole becomes slower and more forcible, the quantity of blood poured into the aorta is increased, and the intraventricular pressure rises At that moment disturbance of conduction may be observed (3) The heart beats are accelerated, the quantity of blood is diminished, and intraventricular pressure falls this is the toxic phase Study of electrocardiograms has thrown light on the action of digitalis, but the ultimate proof is clinical The promiscuous prescription of digitalis for every form of cardiac arrhythmia, whether organic or purely functional, is unjustifiable Vaquez insists that digitalis is of little value in mitral regurgitation until cardiac dilatation is so advanced that there is definite oedema Similarly in aortic regurgitation digitalis is not indicated until arrhythmia occurs with symptoms of secondary dilatation He holds that the fear that digitalis will raise the blood pressure in these cases is illusory, and may be very prejudicial to the patient's welfare The drug should not be withheld in the belief that it has produced or increased bigeminism or arrhythmia, on the contrary, as the drug acts it is usual for the rhythm to be restored Permanent bradycardia definitely contraindicates digitalis Vaquez considers that the use of small doses of digitalis is forbidden by logic and experience, and that the dangers of its cumulative effect have been exaggerated He cites the case of a man suffering from high blood pressure with cardio renal derangement and generalized oedema who had had 5 drops of digitaline solution daily for a long period without improvement The drug was withheld for ten days, the patient then received 40 drops in one dose, followed by 10 drops on each of the next two days After forty eight hours there was abundant diuresis, and the week he passed 740 ounces of urine and the oedema disappeared

Radiology and Electrology.

360 Radium in Carcinoma of the Uterus.

H Schmitz (*Urol and Cutan Rev*, August, 1924, p 447), from a study of 418 consecutive cases of carcinoma of the cervix treated by radium has come to the following conclusions (1) Patients with carcinoma free from necrosis and of limited extent may be safely given the total radiation dose within the shortest time practicable (2) Patients with extensive and necrosing carcinoma should be treated by fractional doses at definite intervals At the first course a dose should be applied which will arrest the haemorrhage and the necrosis and temporarily check the growth of the carcinoma As soon as the patient has passed the period of radium intoxication the balance of the radiation dose may be applied The danger of radium intoxication is thus reduced (3) Patients with extensive carcinoma almost filling the small pelvis or with large necrosing areas and advanced cachexia should not be subjected to a full course of radium treatment and one should be content to arrest the bleeding by a small dose of filtered radium (4) Recurrences following the application of a correctly measured and full radium dose should not receive further radium treatment as the tissues are now refractory to the rays and have lost their recuperative powers *In such cases ulceration and necrosis of the* normal tissues often follow the reapplication of radium

361 Radium Treatment of Cataract

McKee and Swett (*Amer Journ Ophthalmol* August, 1924, p 587) report upon a series of 25 cases of incipient cataract which were treated by radium A dose of 10 mg hours was applied twice a week for eight treatments, the same dose was then applied once a week for eight treatments and subsequently every two weeks Their conclusions are *that in no case was any definite permanent improvement* obtained Some of the patients said they were better shortly after the treatment but such improvement probably depended upon psychological causes as no alteration such as absorption of the opacities was seen The application of the radium caused no apparent injury to any of the structures of the eye apart from an occasional slight erythema of the lids

362. Diagnosis of Biliary Calculi

P Ligniac and A Devois (*Journ de Radiol et d Electrol* July 1924 p 307) state that French *radiologists* were surprised at the American statistics which showed 80 per cent of successes in skiagraphy of biliary calculi The authors consider that the success of American radiologists is almost entirely due to the fact that while European patients are unwilling to allow more than fifteen to thirty minutes for radiographic examination American patients do not hesitate to go *into hospital for four to eight days for diagnostic* purposes During this period the radiologist has ample opportunity to examine the patient every day as often as he likes, and in any position that he deems necessary, consequently as many as twenty to forty skiagrams may be taken Since the adoption of American methods Ligniac and Devois are satisfied that without special preparation the multiplication of films will enable the great majority of biliary calculi to be demonstrated The authors give skiagrams of three typical cases *in married women* in whom the suspected calculi were demonstrated only after a series of skiagrams had been taken In their third case a deformity of the duodenum diagnosed as due to periduodenitis was shown to result from pressure by a large gall stone which had been invisible previously They conclude that it is not only useful but also essential to take as many films and screenings as may be required for diagnosis

363 X ray Diagnosis of Acute Osteomyelitis

I W O'Brien (*Boston Med and Surg Journ* September 11th 1924 p 484) states that an unqualified diagnosis of this disease by x rays is fallacious The changes taking place are chiefly microscopic and a skiagram is a photographic visualization of the varying densities of a substance or substances exposed to x rays The progress of the disease is too rapid for the production of gross changes in the density of the bone During the past year O'Brien has seen an increasing number of cases of acute osteomyelitis in which he had to report No x ray evidence of bony changes recognized This appeared to act as a deterrent to the surgeon he therefore restates the cardinal signs of acute osteomyelitis, and urges that the diagnosis should be made on the general and local clinical symptoms especially a differential blood count since marked leucocytosis occurs usually within six or eight hours from the onset of pain He adds that x rays are of the greatest value in atypical bone lesions near joints simulating acute osteomyelitis and cites the case of a 15 year old boy with a history of a fall on the knee one week before, followed by pain in the thigh A skiagram showed such gross bony changes that it was evidently either a chronic osteomyelitis or a malignant bone tumour it proved to be a sarcoma The author quotes Starr's observation that 'x rays are of no assistance in early *diagnosis, but qualifies his as follows* With the clinical signs present and an x ray examination that shows no positive bone changes the diagnosis is clinched and surgery is indicated to wait for bone changes is folly

Obstetrics and Gynaecology

364 Dysmenorrhoea and Bicornuate Uterus.

C G Noë (*Nederl Tijdschr v Geneesk*, September 27th, 1924 p 1606), who records an illustrative case states that uterus bicornis is due to a disturbance of development in the second month of intrauterine life during which period the Mullerian ducts are hollow The cause of the dysmenorrhoea frequently associated with a bicornuate uterus is not always to be found in the rudimentary condition as is generally supposed The uterus may be removed under the belief that the symptoms may disappear but the patient returns some time after with the same symptoms as before Noë considers that the cause of dysmenorrhoea associated with bicornuate uterus, when the uterine mucosa is histologically abnormal, is both psychical and ovarian and that when the mucosa is normal and there is an absence of infantilism the cause is entirely psychical In both cases the malformation has no causal significance, unless damming back of the uterine *secretion occurs in the rudimentary cornu in which* case there is a mechanical cause for the condition Not infrequently a bicornuate uterus is associated with other abnormalities, which may lead to a wrong diagnosis Thus a pelvic kidney may be mistaken for an ovarian tumour If the bicornate uterus is not diagnosed the dysmenorrhoea may be attributed to a tumour, and the true condition is not discovered until laparotomy Noë's patient was a nullipara aged 24, who had always had violent pain during menstruation, which occurred every four weeks and lasted about eight days during which she lost much blood The first period had occurred at the age of 14 Several practitioners including a specialist had made a diagnosis of bilateral ovarian tumour On examination by Noë a diagnosis was made of left pelvic kidney right movable kidney and a bicornuate uterus with a rudimentary left cornu Operation which was carried out under sacral anaesthesia confirmed this diagnosis The *rudimentary cornu* was removed As diuresis was not affected nephropexis was not considered necessary

33 The Blood in Pregnancy Toxaemias.

C W O Bunker and J J Mundell (*Journ Amer Med Ass oc*, September 13th, 1924 p 836) have investigated the chemistry of the blood in pregnancy with a view to obtaining some warning sign of impending toxaemia They were surprised to find no appreciable change in undoubted cases of eclampsia Some patients with toxic symptoms, but without convulsive seizures appearing, to be imminent gave evidence of a decided nitrogen retention in the blood and the authors consider that the combination of blood examination clinical picture, and subsequent *examination some months later*, justifies them in classifying toxic cases into eclamptic and nephritic toxaemias They conclude that if nitrogen retention is present in a case of pregnancy toxaemia either in the *case of the non protein nitrogen or of the uric acid it strongly* suggests that nephritis is the predominating factor

366 Radioscopy in Obstetrics

M N Moss (*Minnesota Med* vol 7 No 9 p 526) is an enthusiastic advocate of the use of x rays in obstetrics especially during the last month of pregnancy in the case of all primiparous patients and also of multiparae in whom some problem is present By their use (1) the normality or otherwise of the relationship between the head and pelvis can be determined and thus large head can be recognized and dealt with (2) multiple pregnancy can be discovered (3) the foetal position and presentation can be ascertained (4) a monstrosity may be diagnosed—a point of great importance in the after treatment since if any difficulty is encountered at labour perforat on of the head will be performed in preference to a difficult forceps delivery symphysiotomy, or Caesarean section (5) death of the child can be recognized by the detection of overlapping of the cranial bones which gives the head an irregular outline (6) a certain diagnosis of pregnancy can be made in some obscure cases He adds that x rays used carefully are in no way harmful to the baby and are especially useful in any case in which there is a prospect of difficult labour or Caesarean section

367 Fibromyomatosis of the Corpus Uteri

H L Murray and E Glynn (*Brit Journ of Obstet. and Gynaecol*, Autumn Number, 1924, p 398) describe a case in which the whole of the body of the uterus was the seat of a diffuse fibromyomatous change No isolated or encapsulated tumour nodules were present, the cervix was completely unaffected, and no trace of adenomyomatous tissue was found A similar case has been described by Cullen under the name "general myomatous tendency," but the authors suggest the term "complete fibromyomatosis" Histological examination of the specimen in their case showed remarkable vascularity with numerous capillaries and arterioles of an embryonic or *naevoid type, these conditions are probably associated with* the genesis of the morbid condition The patient, a woman aged 31, had had menorrhagia and aching in the back, hips, and groin for six or seven months, the rounded enlarged uterus was 6 inches long and 5½ inches broad, and together with the appendages weighed nearly 3 lb. Uninterrupted recovery followed the removal of the uterus.

368 Treatment of Severe Dysmenorrhoea

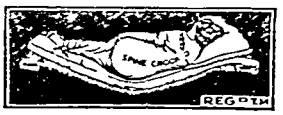
F. A Cleland (*Amer Journ of Obstet and Gynecol*, September, 1924, p 337) has found that in severe dysmenorrhoea the administration of ovarian, thyroid, pituitary, corpus luteum, and mammary extracts, alone or in combination, is no more effective than exhibition of iron, aloes, strychnine, and manganese In 230 cases of severe disabling dysmenorrhoea, in 117 of which the patients were unmarried, he has had good results from an operative treatment of which the essential step is the division of the muscular fibres at the level of the internal os, with the object of causing the nulliparous to resemble the parous uterus One is apt to forget, he remarks, that essential dysmenorrhoea is always cured by childbirth Dilatation to No 10 or 11 (Hegar) having been effected, two lateral incisions about 1/12 in to 1/16 in are made with a blunt pointed bistoury in the internal os, dilatation is now continued to 14 or 15 To prevent subsequent contraction the uterus and cervix are firmly packed with iodoform gauze, which is left undisturbed for eight days The strictest aseptic precautions are, of course, necessary A slight rise of temperature usually occurs on the second day Twenty-nine of the author's patients were only partially relieved, and eight were no better after this operation

Pathology.

369 A Bipolar Theory of Cancer

G W Crile (*Annals of Surgery*, September, 1924, p 289) urges the importance of considering the struggle for survival between the cancer cell and the normal cell, and of studying their nature and structure, so as to discover the physical differences that enable the cancer cell to multiply at the expense of surrounding tissues He compares the phenomena of fertilization with those of malignant cell growth "the whole histologic picture of malignancy indicates that it is primarily nuclear in origin" He believes that as the process of cancerous cell division is analogous to the segmentation of fertilized cells certain facts show that cancer falls within the domain of the electro-chemical, or bipolar, theory which is said to apply to normal living processes Certain analogies exist, according to Crile, between cancer and pyogenic infection Neither process usually attacks tissues of "high oxidative capacity," such as heart muscle, voluntary muscle, cerebral cortex, normal thyroid, liver, kidney, or spleen, they rather attack regions where the "cellular defence" is weaker Once the invading force of cancer cells or pyogenic organisms has passed the first line of defence it takes the path of least resistance—namely, the lymph channels and connective tissue—*rather than attacking solid cellular organs* Both cancer and septic infection are opposed by vigorous metabolic activity in the defending structures Crile has come to the conclusion that (1) the difference between the living and the non-living tissues depends on the accumulation of free energy on the di-electric lipoid films which surround the nucleus, the cytoplasm, and the numerous spherules within the cells (2) the charges are derived from oxidation, (3) intracellular oxidation is governed by the differences in energy potential between the nucleus and the cytoplasm, (4) therefore cellular growth and special function are both dependent upon structure and energy potential This interpretation of cancer assumes that the difference between the cancer cell and neighbouring cells of lower potential is analogous to the difference between the unfertilized and the fertilized ovum The analogy ends with the establishment of cell division, for cancer cells have little or no differentiation Crile states that if this biophysical interpretation be correct *cancer tissue* must fulfil the following requirements (1) the *cancer cells must* have a high storage capacity for electric charges, (2) the conductivity of cancer tissue must show specific variations *from that* of normal tissues—that is, the lipoid films (*a*) of cancer cells, (*b*) of normal cells, and (*c*) of fertilized cells would take electric charges in a direct ratio to the combined surface area of their lipoid films He adds that the investigations of his collaborators tend to establish this theory of cancer

370. The Serological Grouping of Streptococci from Scarlet Fever



G H Eagles (*Brit Journ Exper Path*, August, 1924, p 199) examined 51 strains of haemolytic streptococci, of these 19 came from cases of scarlatina, 13 from cases of puerperal sepsis, 5 from cases of erysipelas, and 14 from miscellaneous sources Against one or more strains from each of these groups immune serums were prepared by injecting rabbits first with heat killed and later with living organisms The suspensions for agglutination were made up by suspending the deposit from a centrifuged broth culture, twenty four hours old, in broth of pH 7 6, shaking vigorously, and standardizing to a fixed opacity All serum dilutions were prepared with the same lot of broth as was used for making the suspensions The tubes were incubated in a water bath at 56° C for two hours and read immediately The results showed quite clearly that the scarlatinal organisms formed a group of their own, *with only one exception all of the* scarlatinal strains were agglutinated by each of the seven serums prepared against strains of scarlatinal origin, whereas they responded only slightly, if at all, to any of the serums prepared against organisms of non-scarlatinal origin Having in this way confirmed the findings of other workers, he set himself to trace the fate of streptococci in the throats of patients recovering from scarlet fever Throat swabs from 11 such cases were cultured on blood agar at intervals of three or four days, 10 colonies picked, and each tested with an agglutinating serum prepared against a scarlatinal strain On the whole it was found that the haemolytic streptococci tended to diminish in numbers after the second week, but more important than this was the loss in agglutinability which they displayed whereas the organisms which were isolated during the early phase of convalescence generally agglutinated highly with the specific serum, those isolated during the latter part were agglutinated hardly at all The explanation of this may lie in the fact that the *Streptococcus scarlatinae* is replaced by other types of streptococci during convalescence, or that under the influence of antitoxin generated by the patient the *Streptococcus scarlatinae* suffers an injury which alters its specific antigenic properties The author seems to favour this latter view

371 Bacteriology of Scarlet Fever

F A Stevens and A R Dochez (*Journ Exper Med*, October, 1924, p 493) describe the isolation of a group of streptococci which agglutinates with scarlatinal immune serums These streptococci have been recovered from the throats of 65 per cent of cases of scarlet fever during the first week of the disease, and also from the throats of patients at the termination of quarantine—thirty days These carriers of specific streptococci are usually those in whom tonsillar inflammation has not entirely subsided The authors suggest, as a result of their findings, that the complications occurring in scarlet fever are either due to the original scarlatinal strain of streptococci or may be the result of a secondary infection with pyogenic strains of streptococci Both contingencies were shown to occur

372 The Pathogenesis of Purpura Haemorrhagica

M Casten (*Il Policlinico*, October 1st, 1924, p 510), after referring to the numerous classifications of purpura haemorrhagica and the various theories as to its etiology and pathogenesis, quotes two cases observed by him, which in his opinion go a long way towards supporting the nervous theory of its origin Both patients were the subjects of uterine sclerosis, and died of terminal pneumonia At the necropsy marked changes were found in the medulla at the level of the superior lateral sympathetic nucleus, the rest of the nervous system was healthy Gordon recorded a similar case of purpura where changes were noted in the corresponding part of the medulla In all cases of purpura there is probably an infection the toxin of which has an elective affinity for this part of the medulla The symmetry and radicular distribution of the rash is also suggestive of a peripheral lesion There is nothing extraordinary in suggesting that a toxin, like other poisons, should show a preference for one particular part of the body.

The old fashioned mattres sags—the digestive organs are distorted—Result Ill health Restlessness and bad sleep

BEDTIME

The old fashioned bed is a fearsome adventure—it sags into a hollow—crooks your spine—distorts your digestive organs—you toss and turn and get up tired and cross

With a Staples Mattress bedtime is a luxury—as you lay down it receives you and moulds itself supportingly into the curves of your body—it softly holds on in a straight health giving position—induces sleep and lulls you to slumber You get up fresh and happ

BOVO-LACTIN & MALNUTRITION

Effective nutrition is admittedly one of the greatest factors in healing protracted or virulent types of disease, and it is also the greatest preventative of disease in cases of debility and exhaustion

In Bovo-Lactin the late Dr E C Hort has given to the Medical Profession the most effective restorative available for the dietetic requirements of modern therapeutics

It is manufactured from purified ox blood, milk solids, and carbohydrates by a method which ensures that the finished products are absolutely free from all harmful organisms

It has a high protein, vitamin and iron content

It contains neither preservatives nor drugs It is not affected by climate or temperature

The full content of hæmoglobin and perfect freedom from bacterial contamination, *without the use of Preservatives*, is ensured by the process evolved by the late Dr Hort for the special preparation of ox-blood, which forms one of the ingredients of the preparations

Inasmuch as it is digested and absorbed with the utmost facility, it is the perfect dietary for use in all those conditions, the treatment of which demands an easily assimilable nutrient and an immediate stimulant

Bovo-Lactin is prepared in three forms—

INVALID BOVO-LACTIN (Powder)

Indicated in the acute stages of illness pneumonia influenza gastric disorders colitis fevers toxæmia and in post-operative states before other nourishment is normally given

The long life battery

Delay is Dangerous

Battery life and human life have much in common

Properly fed and cared for the battery on your car will do its work cheerfully for a prolonged period If it is neglected and ill nourished it becomes an emic and will die very soon

Batteries on Doctor s cars frequently suffer from in sufficient charging to keep the cells in good condition Your nearest Exide Service Agent will arrange for the loan of a battery whilst your own set receives attention in a periodical bench charge

What

The "Curtis" Abdominal Support

really does!

"The Belt —

1 Aids the Abdominal muscles to support the viscera and helps the large intestine to rise when it contains paraffin
2 Takes up the work of the Abdominal muscles when they fail from fatigue
3 Prevents kinking in the upright posture when there are bands
4 Controls the portal circulation by preventing the portal system from having too full a blood supply Thus the belt clears the mind and improves the power of con centration in so far as these have been affected by a deficient cerebral blood supply —*Vide* CHRONIC INTESTINAL STASIS (A Radiological Study) by Dr A. Workmen's Compensation (SILICOSIS) ACTS

REFRACTORIES IN USTRIES (SILICOSIS) SCHEME

Under the revised Scheme for the Refractories Industries which is about to be issued in accordance with the recommendations of the Departmental Committee on Workmen's Compensation for Silicosis the Home Secretary expects shortly to APPOINT A MEDICAL BOARD to undertake the periodic and other medical examinations required under the Scheme This Board which will have its centre at Sheffield, will consist of two whole time Medical Officers, the senior of whom must have had not less than ten years practice in the diagnosis of respiratory diseases with special experience of silicosis

The scales of salary would be in the case of the senior Medical Officer £900 per annum rising by £50 a year to £1 000 and in the case of the junior Medical Officer £700 rising by £25 a year to £900 The appointments would be for a definite term—not less than three years—and would be capable of renewal but would be subject to termination at the discretion of the Secretary of State Travelling expenses and subsistence allowances would be paid

The salaries &c, of the Medical Board would be payable out of the Refractories Industries Compensation Fund but the Board would work under Instructions issued by the Secretary of State and would be directly responsible to him

Further particulars and forms of application may be obtained from the Industrial Division Home Office Whitehall S W 1 Applications should be made not later than the 9th November 1924

The *original* preparation which has the property of stimulating the excretion and arresting the formation of uric acid to a degree hitherto unknown

A large volume of evidence shows the value of Atophan in the treatment of **acute and chronic gout, rheumatism, and all affections associated with the uric acid diathesis**

Atophan is a powerful analgetic, antipyretic, and antiphlogistic, and, in addition, it exercises an astoundingly rapid stimulating action on the hepatic functions

ATOPHAN COMBINATIONS

ICTEROSAN

For catarrhal jaundice, cholangitis, cholecystitis, etc One injection is usually sufficient to produce an immediate flow of bile

In ampoules of 5 c c

ARCANOL

A combination of Atophan and Acid Acetyl Sal, which has proved of great value in influenza and all diseases associated with chill

In tablets of 15 grs

ATOPHANYL

For injection.

The parenteral administration of Atophan in this form is especially indicated in rheumatism, sciatica, neuralgia, neuritis, etc The action is prompt and extremely vigorous

In ampoules of 5 c c

'PITIBULIN'

Trade BRAND Mark

Post Pituitary Extract

Specially prepared for Hypodermic and Intramuscular Injection.

'Pitibulin Preparations are physiologically tested and standardised by the most approved methods, and may be relied upon for purity, constancy, activity and asepsis

NOW ISSUED IN TWO STRENGTHS.

'Pitibulin' Obstetric

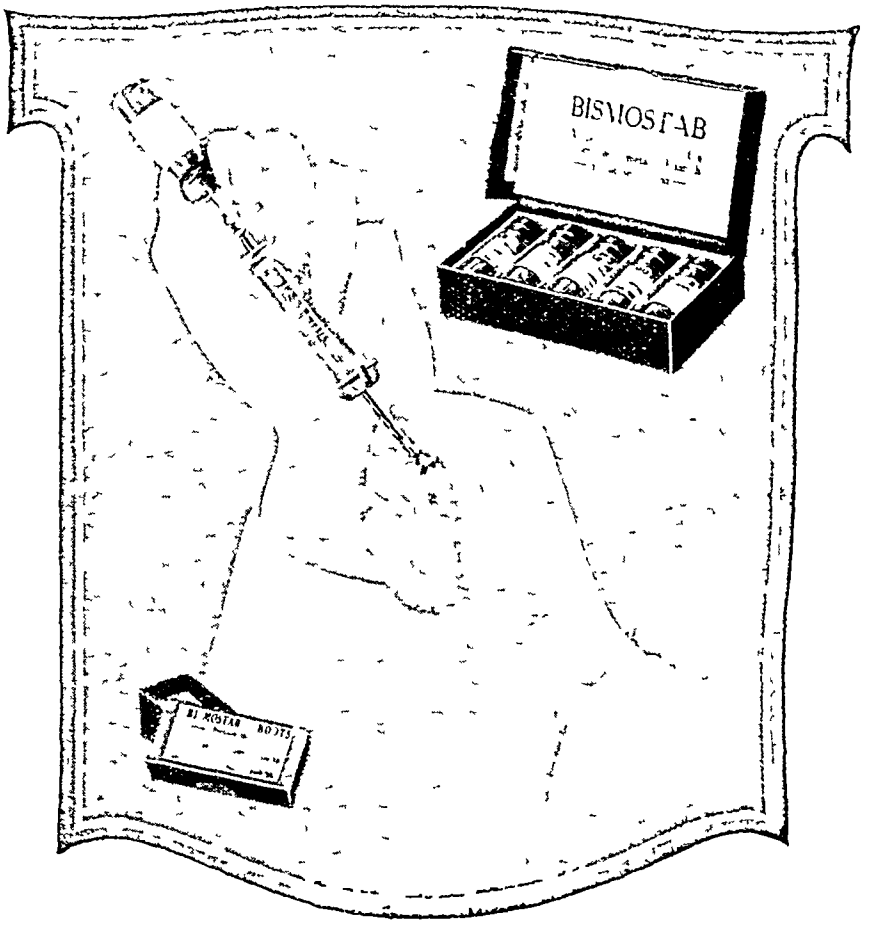
A 10 per cent. standardised extract of infundibular substance as recommended by the Medical Research Council for obstetrical and general purposes Given intramuscularly Pitibulin Obstetric is invaluable for promoting uterine contraction in the second stage of labour and after delivery also for the prevention of post partum hæmorrhage.

Preparations

Azoule Pitibulin Obstetric—½ and 1 c c in each In boxes of 6 and 12.
Azoule Pitibulin with Adrenin—½ c c with gr 1/5 In boxes of 6 and 12.
Azoule Pitibulin with Adrenin—1 c c with gr 1/5 In boxes of 6 and 12

'Pitibulin' Surgical

A 20 per cent. extract of infundibular body This preparation is identical with Pitibulin as hitherto supplied by this House Its use is especially indicated to raise blood pressure in surgical shock and post anæsthetic collapse In very urgent cases it may be administered *per rectum* or intravenously diluted with normal saline.



Preparations.

Azoule Pitibulin Surgical—½ and 1 c.c. in each. In boxes of 6 and 12.

Leaflet giving further particulars will be sent on request

NEW CHEMICALS, DRUGS, AND METHODS OF TREATMENT.

The following are a few brief notes to give a mere outline of the additions

ALKALOIDAL NOTES This chapter contains some very interesting observations regarding "Activated" Alkaloids, and in addition, the description of a series of Alkaloidal Periodides The preparations may, in both cases, be useful additions to the physician's armamentarium

ASPIRIN COMPOUNDS, include therapeutic notes upon the various new halogen derivatives

BISMUTH, ORGANIC COMPOUNDS The "pros and cons" of these competitors to Mercurials, and their chemistry, are described in six pages

COLLOIDAL METALS The chapter contains, as new, Colloidal Calcium, Colloidal Lead, also notes upon the Colloidal Gold treatment of neurasthenia, alcoholism, and the morphine habit

EMETINE and COMPOUNDS Fifteen pages on new bodies in dysentery

ACCESSORY FOOD FACTORS, with practical hints for making preparations to retain the factors unimpaired

CHAULMOOGRA PREPARATIONS New compounds in the treatment of leprosy, tuberculosis, etc

INSULIN, eight pages devoted to technique and clinical experience

QUINDINE and CINCHONIDINE bodies in heart affections

NON-IONISABLE MERCURIALS VACCINES ORGANOTHERAPHY INTRAVENOUS TREATMENT. DANGEROUS DRUGS ACTS INSTRUCTIONS

Fine Pure Wool Sheets

It might be thought that a woollen sheet can only be a modified blanket and therefore not quite suitable but this is not the case

Jaeger Pure Wool Sheets are made of a fabric much lighter and smoother than the flannel which is very often worn next the skin They are in fact as smooth as linen or cotton with the advantage and comfort which wool gives

They are warmer in the winter and cooler in the summer because wool is a slow conductor To the invalid a wool sheet is of special value but anyone of good health who has also tried one never abandons it if only on account of the luxurious ease which a Jaeger Sheet gives

White Wool "Taffeta" Sheets
for Single Bed **43/6** each, for Double Bed **75/-** each

Intestinal Disinfection

No. 10

BACILLUS COLI, BACILLURIA AND URINARY INFECTIONS

Conditions dependent upon infection of the urinary tract by *B coli* are by no means uncommon and present varying degrees of severity from serious suppurative lesions of the kidney to mild bacilluria of little importance

The mechanism of infection by *B coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B coli* are common in urinary infections in the male)

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed and those already located in the urinary tract may be attacked by a urinary antiseptic By the combined administration of KEROL, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B coli* is placed on a rational basis and many cases are cured by this line of treatment when they fail to yield to urotropin alone

For intestinal disinfection, use KEROL CAPSULES (keratin coated) they contain 3 minims of Kerol One to three Capsules may be given three or four times a day after meals

KEROL CAPSULES

Please send for literature and samples which will be sent free to any member of the Medical Profession

A Brief Review of the Theory and Practice of

Ultra-Violet Radiation

We offer to all medical practitioners a copy of our new pamphlet dealing with the theory and practice of photo-therapy—or the therapeutic uses of Ultra-Violet Radiation

In view of the prominence of the subject at the moment, and the fact that photo-therapy is rapidly becoming an important factor in the treatment of disease, this useful review of the entire subject is of absorbing interest

It deals with the various types of radiations employed and the method of their employment It describes the advantages of the various sources of radiation It presents a fully illustrated catalogue and price list of all the most suitable apparatus for the practice of photo-therapy

The above illustration is a typical example from the pamphlet It shows the details of the K B B Mercury-vapour Lamp for local application

The pamphlet is, however, much more than a catalogue It is a useful contribution to the literature of the subject

Send a Post-card for your copy To-day

The Value of Sanatogen in the Treatment of Dyspepsia

In all dyspeptic conditions Sanatogen offers a valuable reinforcement of ordinary therapeutic measures It is highly nutritious, easily absorbed and assimilated, and so bland and non-irritating that even in acute gastritis it is well borne

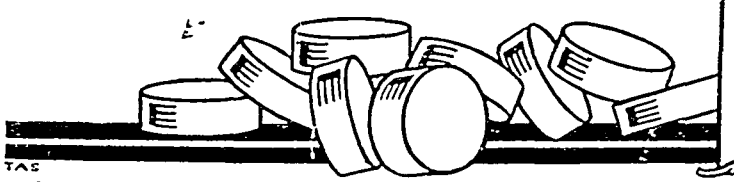
Sanatogen gives rise to no disturbance in the way of pain, vomiting, or flatulence, and is consequently of great value in inflamed and ulcerated conditions of the gastro intestinal tract—such as gastric ulcer, malignant disease of the stomach, and gastric dilatation

Exhaustive experiments have proved that not only is Sanatogen itself completely absorbed and assimilated, but it also secures a better utilization of other food products taken with it For this reason, the tissue starvation to which chronic dyspeptics are liable may be effectually obviated by the use of Sanatogen

SANATOGEN

The True Tonic-Food

A clinical sample of Sanatogen will gladly be sent to any physician upon request to
GENATOSAN, LIMITED, Loughborough, Leicestershire.



It's no trouble.

Hyperol

SIMPLY dissolve a tablet of Hyperol in a measured volume of water. The Value of Marmite in Marasmic conditions

IN many cases of Marasmus the wasted condition of the body has been found to be due not only to malnutrition in the sense that insufficient food had been supplied, but to an inability to assimilate essential fats owing to a deficiency of Vitamin B

Apart from its function as a preventive of Beri-Beri, Vitamin B has a distinct influence upon the normal growth and health of the body Of all the known accessory food factors, it is Vitamin B which promotes the ready absorption of fats and consequently increases the powers of resistance to disease

Medical men will find in Marmite a palatable and readily available preparation and a food richer than any other in Vitamin B It is an extract of yeast extremely pleasant to the taste, and may be recommended to be used in soups, stews, gravies, etc, or in the form of sandwiches

Marmite

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness

TRADE MARK ALOCOL BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition For this reason they are distinctly contra indicated, especially in stubborn cases

Alocol does not neutralize acid it absorbs the excess colloido chemically and at the same time leaves a sufficiency for normal gastric digestion The outstanding advantage of Alocol as an antacid is that it removes from the stomach the excess of the acid radicle (Cl) instead of merely temporarily neutralizing it Alocol can be used for prolonged periods without the slightest harmful effect

"Alocol" is indicated in all conditions in which diagnosis reveals high gastric acidity It is particularly valuable in the treatment of chronic affections of the stomach, the dyspepsias, especially those of pregnancy gastric and duodenal ulcer, gastrosuccorrhea and in conditions characterized by gastralgia pyrosis flatulence, acid eructation and other symptoms common to gastric disease

In cases of CYSTITIS

always prescribe

CYSTOPURIN

(The Ideal Urinary Antiseptic)

The therapeutic action of Cystopurin has been established by clinical, microscopical, and bacteriological research, and numerous authorities are convinced of its superiority to all preparations hitherto available for the internal treatment of Cystitis, Gonorrhœa, and other infective conditions of the bladder—combined with appropriate local measures

Results of Cystopurin in Cystitis

1 Urine becomes clear
2 Offensive odour is lost
3 Subjective symptoms abate rapidly
4 Diminishes amount of bacteriuria

Cystopurin is free from all irritant action and causes no gastric symptoms, and is therefore well tolerated by the patient

A clinical sample and specially prepared medical literature will gladly be sent to any doctor upon request to—

When Phosphates and Fats are needed

When it is necessary that a patient should have extra supplies of these two reconstructive food components, it is often desirable to prescribe them in some palatable form so that any aversion for oleaginous liquids may be overcome

"Skippers," the tiny silvery fish packed in pure first-grade Olive Oil, solve this difficulty to perfection The fish themselves supply the phosphates in an easily digestible form, and their delicate flavour and attractive appearance make them an acceptable vehicle for the nutritious olive oil with which they are impregnated

Skippers are more easily digestible than most fat foods and are free from bones or scales The name Angus Watson on every tin of Skippers is a guarantee of quality and wholesomeness

Even delicate invalids and children can digest and enjoy Skippers, and they are often precisely the form of nutriment needed to build up strength after illness

"Skippers"

NO BONES - NO SCALES

The name ANGUS WATSON on any ready-to-serve food means the best of its kind

ANGUS WATSON & CO LIMITED Ellison House NEWCASTLE UPON TYNE

Roboleine

is a most valuable ally in cases of malnutrition

THE proof of this statement is provided by the fact that the great hospitals and practically all the child-welfare centres have used 'Roboleine' consistently for many years Add to this the testimony of practitioners in general and the extract from the letter of the Governor of the London Hospital which follows, and the evidence is complete

"The effect on some of our anæmic and rickety children has been MAGICAL."—
Governor of the London Hospital

FORMULA:
Marrow from the long bones, Red Marrow from the rib bones of prime oxen, 'Cream of Malt,' Egg Yolk, and Neutralized — Lemon Juice —

CONSTITUENTS:
Animal Fats, Maltose, Diastase, and natural nitrogenous and Phosphoric compounds

Clinical Sample and Literature on request

BAS RELIEF IN WHICH ARE DEPICTED THE YOUNG KING CH'ENG AND HIS UNCLE THE GREAT PIONEER OF CHINESE GOVERNMENT INSTITUTIONS.—King Ch'eng the second sovereign of the Chou dynasty succeeded to the throne while still a minor His uncle and guardian Tan, the Duke of Chou was appointed regent of the empire. Through his wisdom and virtue his organising and administrative abilities he became one of the greatest and most celebrated figures in the whole history of China By his wise counsels he had already aided the late king his brother, in establishing the dynasty and he now gave himself up to consolidating the empire He organised the machinery of state and directed its policy he drew up a code of laws and purified the morals of the people. To him is attributed the authorship of an important work in which are described the ordinances of the empire in Chou times and to which Chinese emperors down to recent times turned for guidance in difficult situations The Duke of Chou was proof against all temptation to arrogate the imperial power to himself Ch'eng honoured his uncle, benefited by his teaching and became a great and good king In instituting a prince of the deposed Shang dynasty as head of the province of Korea, he thus addressed him *Reverently* and carefully you discharge your filial duties gravely and respectfully you behave to spirits and to men the people will be reverently harmonious under your sway Go and diffuse abroad your instructions follow and observe the proper statutes Be a law to your people future ages will enjoy the benefit of your virtue and thus you will make our dynasty of Chou never weary of you.

In the centre of the scene here reproduced the young king is seated on a platform an umbrella held over him by an attendant. On the left kneels Tan Duke of Chou.

A Lecture on ACCLIMATIZATION TO HIGH ALTITUDES

Delivered to University College Medical Society, October, 1924,

by

J. S. HALDANE, M.D., F.R.S.,
Oxford

The great physiological difficulties met with at very high altitudes in the Mount Everest expeditions, and so far conquered, have recently drawn much attention to acclimatization to high altitudes, but apart from this the phenomena of acclimatization, whether to high altitudes or to other unusual conditions of environment, are of the deepest biological interest and significance. In my book on *Respiration*, published two years ago, I discussed this subject piecemeal, but I wish to take this opportunity of reviewing it as a whole in the light of the additional facts revealed by the Mount Everest expeditions and the recent Anglo-American expedition to the Andes.

It was proved quite clearly by Paul Bert nearly fifty years ago that the abnormal symptoms experienced at very low atmospheric pressures such as those existing at high altitudes, are due entirely to the low partial pressure of the oxygen in the air and consequent abnormally low partial pressure of the oxygen supplied to the tissues by the blood. It took about thirty years before the significance of his experiments and reasoning was generally understood by physiologists, but I think I need hardly go back upon this. He was also well aware that considerable acclimatization to low atmospheric pressure occurs, but as to the manner in which this acclimatization is brought about, or the extent to which it could be carried, his knowledge was limited.

Effects of Low Atmospheric Pressure on Unacclimatized Persons

The effects of a temporary exposure to low barometric pressure can be studied conveniently in a steel chamber such as that originally employed for this purpose by Paul Bert. The air of the chamber is exhausted by means of a pump, and the pressure inside regulated by varying the amount of air which is allowed to leak in through a tap. We can also study these effects during ascents in balloons or aeroplanes, or after comparatively rapid ascents, whether on foot or otherwise, to high mountain altitudes.

On going within a few hours to a barometric pressure corresponding to an altitude of as little as five or six thousand feet we first begin to notice that any considerable exertion, such as walking uphill, is accompanied by unusual panting and increase of pulse rate. At three or four thousand feet higher this effect is much more marked, and is commonly accompanied by other more serious effects, showing themselves after a time even during rest. One of these effects is what is known as mountain sickness. Its chief symptoms are nausea, vomiting, and headache, though several hours of exposure are needed before they appear. With greater altitudes or depressions of barometric pressure these effects become more and more marked, and show themselves in more and more persons. More or less of blueness of the lips can also be observed, and various abnormal mental symptoms. Breathing also tends in many persons to become periodic, and sleep to be disturbed. When a pressure of only half an atmosphere is reached, corresponding to a height of about 18,000 feet, the acuity of vision and hearing begin to be distinctly affected, as well as the power of remembering the events which are happening, and forming a clear judgement about them. This loss of sensory and mental power becomes more and more marked as the barometric pressure is further reduced, until at about 25,000 feet or less a condition of complete helplessness, accompanied by very marked blueness of the lips, is commonly produced after a quite short exposure. Power over the limbs, beginning with the legs, fails, the pulse and respirations become rapid but feeble, consciousness is lost, and the condition is one of impending death from failure in the depth of respiration.

Influence of Acclimatization

These symptoms are wiped out completely if, by substituting oxygen for nitrogen in the rarefied air breathed, the fall in the partial pressure of oxygen in the air is prevented, but they can also be prevented or got rid of to a large extent by acclimatization. Persons who ascend gradually day after day, to heights of 20,000 feet or more will probably never experience mountain sickness or any of the other more formidable effects of great altitude; and persons who have gone rapidly to great height and stayed there for several days will recover from the more formidable effects, provided they have not gone too high for acclimatization to occur before their death. The Mount Everest achievement of this year has shown that persons can even reach the height of 28,000 feet without mountain sickness.

Causes of Low Oxygen Pressure in the Arterial Blood

In order to follow the means by which acclimatization is brought about we must first understand the means by which an abnormally low partial pressure of oxygen is produced in the tissues and particularly those of the central nervous system. Paul Bert and others showed that when air with a normal pressure of oxygen in the inspired air the arterial blood is bright scarlet and its haemoglobin almost completely saturated with oxygen during rest it becomes more or less blue, with the haemoglobin imperfectly saturated, when the oxygen pressure of the inspired air is very low. This is due to the oxygen pressure in the arterial blood being no longer sufficient to permit combination of oxygen to a normal extent with the haemoglobin, since oxyhaemoglobin is easily dissociable. Thus the blood reaching the tissues has an abnormally low oxygen pressure. It may, and does, still contain abundance of dissociable oxygen to cover all the normal consumption of oxygen by the tissues, but the pressure of this oxygen is too low, and the observed symptom are evidently due to the low oxygen pressure and not to mere insufficiency in the amount of oxygen in the blood.

The most natural explanation of the low oxygen pressure in the arterial blood is that the oxygen pressure in the lung alveoli is correspondingly low, and that since the passage of oxygen inwards depends presumably on simple diffusion, the arterial blood cannot be saturated to a higher oxygen pressure than that of the alveolar air. This reasoning, however, takes no account of acclimatization or of the fact that between the alveolar air and blood there is a thin layer of living protoplasm which might upset the reasoning altogether by actively driving oxygen inwards into the blood. The suspicion that this may be the case originated with Ludwig and was transmitted by him to his pupil Christian Bohr of Copenhagen, and thence to a pupil of the latter—myself. It is pretty clear that Ludwig's idea was suggested by the experiments of Moreau a French physiologist on the physiology of active secretion of oxygen by the living wall of the swim bladder. I have in my library Ludwig's own copy of one of Moreau's papers. Moreau's work was inspired by the remarkable discovery made at the beginning of last century by Biot. Pasteur's early master that the swim-bladder may contain almost pure oxygen. In a deep-sea fish the pressure of oxygen may be nine hundred times that in the surrounding sea water. Its secreting epithelial cells are thick and cubical while the epithelial cells of the lung alveoli are extremely thin, but for secretory activity to be of great importance in the lungs it would only be necessary for the secreting cells to overcome an oxygen pressure of less than a four-thousandth of that overcome by the cells of the swim-bladder. In considering acclimatization to high altitudes I shall first discuss the evidence for and against active secretion of oxygen inwards, and its relation to acclimatization.

We must first distinguish the oxygen secretion controversy from another one relating to gaseous exchanges in the lungs, and also emanating from Ludwig. He suggested that the process of oxygenation of blood in the lungs may help to expel carbon dioxide, and one of his pupils published experiments which gave some support to this idea.

With the help of the aerotonometer devised by Pflüger, evidence was, however, brought forward by the latter's pupils which seemed to negative Ludwig's idea. Bohr failed also to substantiate it. Finally, however, Christiansen, *Douglas, and I, with the help of far better methods of blood-gas analysis, showed clearly, about eleven years ago, that* Ludwig was right, and our results are now everywhere accepted, particularly as they explained how the aerotonometer experiments of Pflüger's pupils had been fallacious.[1]

Experiments with Aerotonometers

It was Bohr who first, in 1891, brought forward definite experimental evidence in favour of the oxygen secretion theory.[2] He used an improved form of the Pflüger aerotonometer. The arterial blood, which was rendered incoagulable by the injection of peptone or leech extract, was allowed to flow for a short time alternately in and out of two glass vessels connected together above, and containing a gas mixture with which the blood came into contact, so that free diffusion could occur between the blood and gas mixture *before the blood returned to the animal*. It was found that although the pressure of oxygen in the gas mixture usually *fell below that of the alveolar air*, it occasionally rose distinctly higher. Bohr regarded these results as showing that active secretion of oxygen may occur in the lungs.

The investigation was then taken up by Fredericq.[3] Using a slightly simpler form of aerotonometer, permitting less interference with the animal's circulation, he found that, when sufficient time was given for complete diffusion equilibrium to occur between the gas mixture and arterial blood, the oxygen pressure in the gas of the aerotonometer was, in his experiments, always very considerably below that of the alveolar air. He therefore concluded that there is no real evidence for oxygen secretion, and that the apparent positive results of Bohr were due to experimental error. The results of Fredericq's experiments are definite and unmistakable, and they were fully confirmed by later experiments made by Krogh with a still better apparatus.[4] They certainly showed no evidence of oxygen secretion, but they had a further significance, which to my mind has emerged more and more clearly as our knowledge of respiration and the blood gases has increased. That significance is that neither the aerotonometer method nor the corresponding method of analysing the gases of arterial blood and calculating the oxygen pressure from the results is reliable in testing the theory of oxygen secretion.

On examining Fredericq's results we find that they give two values, one being the pressure of carbon dioxide, and the other of oxygen, in the arterial blood. For carbon dioxide the value corresponds to an excess of about 3 per cent of carbon dioxide in air, while for oxygen it corresponds to a deficiency of about 8 per cent. *If we assume*, as we can do with practical certainty, *that the pressure of carbon dioxide corresponded to the percentage of carbon* dioxide in the alveolar air, it is quite impossible that the deficiency of oxygen can also have corresponded to the deficiency of oxygen in the alveolar air. The respiratory quotient would be a *quite impossibly low one*, particularly in some of the experiments. We thus seem at first sight driven to conclude, as Fredericq did, that even when an animal is at rest, and breathing pure air at ordinary pressure, the oxygen pressure in the blood and alveolar air may be far *from coming into diffusion equilibrium* with one another. But if this is so even during rest what would happen during muscular exertion, when more than ten times as much oxygen has to be taken up *from the alveolar air*? The arterial blood would certainly be of a deep blue colour *which is not the case*, and a simple calculation shows that the absorption of the amount of oxygen which is actually absorbed during muscular work at a high altitude *would be quite impossible*.

It is thus perfectly evident that in these experiments some cause was preventing the gas pressures in the arterial blood passing through the aerotonometer from representing the degree of equilibrium which is reached between the oxygen pressures in the alveolar air and blood passing through the alveoli, so that neither the aerotonometer method nor the corresponding method of inferring the oxygen pressure in the arterial blood from the degree of saturation with oxygen of the haemoglobin in it could possibly give reliable measurements relating to the question of oxygen secretion. We thought for long that this cause was most probably that during the period which elapsed between saturation of the blood in the lungs and its passage through the aerotonometer, or into the blood gas apparatus, a certain amount of oxygen enters into stable chemical combination. The real cause was, however, revealed quite clearly by the investigations published in 1919 by Meakins, Priestley, and myself on the effects of shallow breathing, and by the light which our results threw on the composition of arterial blood.[5]

Uneven Composition of the Alveolar Air

We found that when the breathing is shallow, even if it is very rapid, and even if the oxygen percentage in the mixed alveolar air is above normal owing to great increase in the amount of air breathed with the rapid respirations, unmistakable symptoms of oxygen shortage are produced, and are promptly relieved by raising the oxygen percentage in the inspired air. The evident explanation of these facts is that the air in the different alveoli, instead of being uniform in composition as had *formerly been* assumed, varies in composition at different parts of the lungs. A sample of alveolar air, taken by *the ordinary method* introduced by Priestley and myself, represents, therefore, only the mean composition *of the air in the deep alveoli*. *In* some alveoli the oxygen *percentage must* be much lower than the mean and the carbon dioxide percentage higher, and conversely in *other alveoli*. With shallow breathing this irregularity is much exaggerated, owing to the uneven manner in which *different parts* of the lungs expand, as was pointed out by Sir Arthur Keith.

Owing to the different shapes of the dissociation curves of the oxyhaemoglobin and the bicarbonate, in the forms of which the oxygen and carbon dioxide in the blood are *respectively combined, the irregularity* will affect quite differently the partial pressures of carbon dioxide and oxygen in the mixed arterial blood. This can be seen at a glance on looking at the two curves, which are reproduced side by side in our paper. The carbon dioxide pressure in the mixed arterial *blood* will depend simply on the average carbon dioxide pressure in the alveolar air, since the effects on the blood of excesses of carbon dioxide in some alveoli are neutralized by those of the deficiencies in others. But a deficiency of oxygen brings the blood down the steeper part of the *dissociation* curve, while an excess brings it along the flatter part. The inevitable result is that the pressure of oxygen in the mixed arterial blood is lower, and may be far lower, than that of the mixed alveolar air. This effect will also, it can be seen, be much exaggerated *in its effect* on the percentage saturation *of the* mixed arterial blood with oxygen if the mean oxygen pressure in the alveolar air is low, as at high altitudes. An experiment of Krogh's on an animal breathing a low percentage of oxygen shows this clearly. We have thus a simple explanation of why, *before acclimatization occurs*, there is far more cyanosis than could otherwise be accounted for.

It is an entire mistake to suppose that this want of correspondence occurs only during shallow breathing, though it is much exaggerated by *shallow breathing*. Whether we use aerotonometers or the method of inferring the oxygen pressure of the arterial blood from the degree of saturation of the haemoglobin in it, as shown by blood-gas analysis, the result always is that under normal resting *conditions* the oxygen pressure *of arterial blood is below* that of the mixed *alveolar air*. *In my own case*, for instance, blood-gas analysis showed an oxygen pressure about 14 per cent below that of the alveolar air. Perhaps no experiment brings the facts home to us more clearly than observations on the effects of *holding the breath*. If we distend the lungs with a *deep breath of air*, and then *hold the breath* as long as we can, we find, by repeating the experiment with air enriched with oxygen, that it is not merely excess of carbon dioxide but also as Leonard Hill and Flack first found want of oxygen that has limited the time during which the breath can be held. With the enriched air the breath can be held far longer. Douglas and I found that the current

ment still existed although the mixed alveolar air at the breaking point contained more oxygen than normal, while Davies and Meakins proved by analyses of the arterial blood that at the breaking point the oxygen pressure in the arterial blood is far below that of the mixed alveolar air

The Carbon Monoxide Method of Investigation

The fact that it is quite impossible to obtain reliable results as to the presence or absence of oxygen secretion by the aerotonometer method, or by analysing the arterial blood, led me to introduce a quite different method of experiment This method depends on the fact that oxygen and carbon monoxide compete with one another in accordance with a perfectly sharp and definite physical law when they both strive to enter into combination with the haemoglobin of the blood The equilibrium which is reached depends on the relative pressures of the two gases, so that if we know (1) the percentage saturation of the blood with carbon monoxide when equilibrium is reached and (2) the pressure of carbon monoxide, we can infer the pressure of oxygen It is evident that by this method we can infer the mean pressure of oxygen, not in the mixed arterial blood but in the unmixed blood leaving the lung alveoli This is the method used, first by Lorrain Smith and myself later, in an extremely careful series of experiments, by Douglas and myself with greatly improved technique[6] and later still in the Anglo-American expedition to Pike's Peal by Douglas, Yandell Henderson Schneider, and myself for the investigation of acclimatization to high altitudes[7] For further details of the method I must refer to the original papers, or to my book on *Respiration* I need only give here the results which were reached

Experiments at Normal Atmospheric Pressures

We first investigated partly on man and partly on mice, what happens under perfectly normal conditions at ordinary atmospheric pressure during rest The experiments showed unmistakably that very exact diffusion equilibrium is reached between the oxygen in the alveolar air and that in the blood This is what one would expect on purely physical grounds and the experiments showed clearly the fallacy in the experiments of Fredericq Krogh and others who have inferred from experiments with the aerotonometer or from analyses of arterial blood that sensible diffusion equilibrium does not occur The result is what one would expect on physiological grounds for oxygen secretion if it occurred would be of singularly little use since it could increase but little the normal saturation of the arterial blood with oxygen

We then examined in mice what occurs in fairly prolonged exposure to the oxygen shortage of carbon monoxide poisoning The result was that as the oxygen shortage increased the mean oxygen pressure in the blood leaving the alveoli gradually rose high above that of the alveolar air and even the inspired air With oxygen shortage produced rapidly in man by lowering the percentage of oxygen in the inspired air the oxygen pressure in the blood leaving the alveoli rose only very slightly above that in the alveolar air This is in good agreement with the fact that acclimatization to the low oxygen pressure in the air at a high altitude requires a considerable time

Our next step was to examine what happen during muscular exertion It is during muscular exertion that we should expect to find oxygen secretion coming into play The reason for this inference is that during hard muscular exertion shortage of oxygen occurs very readily and this shortage in so far as it affects the breathing must be due to deficient saturation of the arterial blood with oxygen The breathing during hard muscular exertion becomes usually of the type produced not by mere excess of carbon dioxide, but by a combination of this with shortage of oxygen In other words, the rate of breathing and volume of air breathed increase out of proportion to the rise of carbon dioxide in the alveolar air and finally the percentage of carbon dioxide in the alveolar air falls below normal We have also now direct evidence first obtained by Harrop, that with hard enough work there is a great fall in the oxygen pressure of the arterial blood Further indirect evidence is furnished by the fact that the doing of very hard work is greatly facilitated by air in which the percentage or pressure of oxygen is raised

The physiological function of oxygen secretion (if it occurs) during muscular work is presumably to prevent or diminish the fall which would otherwise occur in the oxygen pressure of the arterial blood Hence it is not to be expected that an actual rise above that of the alveolar air will occur readily during muscular work when active secretion occurs On the other hand it is evident from our observations of oxygen secretion in connexion with carbon monoxide poisoning that the stimulus to oxygen secretion originates in the tissues, not in the lung, and is probably due to some substance carried to the lung or possibly the central nervous system, from tissues which are short of oxygen Hence we thought that the best chance of producing an actual rise of oxygen pressure in the blood leaving the alveoli would be to do exhausting work with only one arm so as to furnish the stimulus to secretion without at the same time so raising the consumption of oxygen in the body as to occasion, apart from secretion, any appreciable fall in the oxygen pressure of the arterial blood Our expectations were justified, and we found a very considerable rise in the mean oxygen pressure of the blood leaving the alveoli over that of the alveolar air This occurred in every experiment and was quite unmistakable It seems probable that the occasional positive result in Bohr's experiments depended on stimuli arising from interference with the circulation in his method of experiment

If the response to want of oxygen by oxygen secretion in the lungs is a normal response we should expect to find that it becomes more ready and powerful with use just as other functions are improved by use Evidence on this point has been furnished by a series of observations made by Professor Briggs of Edinburgh[8] While experimenting with mine-rescue apparatus during the use of which air greatly enriched with oxygen is breathed, he found that men who are in good muscular training receive hardly any benefit from the enriched air during comparatively hard muscular work Men who are not in training receive on the other hand great benefit—a fact which is well known to me from personal experience The difference can be measured easily by analyses of the expired air or alveolar air and these are evidently a good test of physical training It thus seems evident that a man in good physical training can prevent shortage of oxygen in his arterial blood, and active secretion of oxygen is the only known means of doing this

Experiments on Pike's Peal

The final experiments were made during our stay of some weeks on the summit of Pike's Peak at a height of 14,000 ft The results were again quite definite The mean oxygen pressure of the blood leaving the alveoli was found 6 b, after, but not before, acclimatization had occurred at least 50 per cent higher than in the alveolar air, and only a little lower than at sea level Let us see what this result did and did not mean It meant that the mean oxygen pressure of the blood leaving the lung alveoli was 50 per cent higher than in the alveolar air, but certainly not that the mixed arterial blood as we find it in an artery or in blood taken from an artery had almost a normal oxygen pressure or saturation with oxygen The whole of the phenomena of acclimatization are dependent on the continued stimulus of oxygen shortage in the blood as we said again and again in the Pike's Peak report

We thought at the time when the report was written that the shortage was almost entirely due to increased oxidation in the blood during the period which elapsed between its leaving the lungs and reaching the tissues for we did not then know of the irregularity of the composition of the air in the lung alveoli and the consequence of this which I have already pointed out With a lowered partial pressure of oxygen in the inspired air the consequence must be far more marked as already remarked and this accounts for the very marked blueness of unacclimatized persons on Pike's Peak Mealins, Priestley, and I found that in neurasthenic cases suffering from the nervous disturbance of respiration, which makes the breathing

abnormally shallow and rapid (so called "D A H" or "disordered action of the heart"), even a slight diminution of atmospheric pressure, such as produced no appreciable reaction whatever in normal persons, produced the most urgent symptoms when these patients were tested in a steel chamber.

In the persons carefully observed on Pike's Peak—at least in the cases of Douglas, Yandell Henderson, and myself—the shortage of oxygen in the arterial blood was so slight after acclimatization that we could observe no diminution at all in the normal redness of the lips, though we were all very distinctly blue in the lips during the day or two which elapsed before acclimatization, when we were still suffering from mountain sickness. In the many persons who came up temporarily by train, on donkeys, or on foot, the blueness was also nearly always well marked, and sometimes not only extreme, but accompanied by clouding, or even complete temporary loss of consciousness. In unacclimatized persons who were walking up along the railway track and who were not in physical training the cyanosis during the exertion became extreme, and rests were necessary every few steps.

It is well known to mountaineers that persons who are in good training are much less susceptible to mountain sickness than others. In the light of Briggs's observations and their interpretation we can now understand this readily, for persons in good training are also ready to secrete oxygen.

Increased Percentage of Haemoglobin at High Altitudes

I must now pass on to the discussion of other factors in acclimatization. The best, and longest, known of these is increase in the percentage of haemoglobin in the blood. This must help in the following manner. With a higher percentage of haemoglobin in the blood there must be, other things being equal, a larger store of dissociable oxygen in the arterial blood. This is of no direct help in combating the symptoms, which, as we have already seen, are due to deficiency in the partial pressure of the oxygen, but it must help indirectly in the following manner. With a given disappearance of free oxygen in the tissues the pressure of oxygen will not fall so low if there is an increased proportion of haemoglobin in the blood. In this indirect way the mean pressure of oxygen will be kept higher, and it is the pressure of oxygen round the living tissues, and not merely in the arterial blood, that matters.

The extent and the rapidity with which the haemoglobin percentage in the blood increases in different individuals are very variable, and the more essential physiological changes during acclimatization may be almost complete before there is much increase in the haemoglobin. The mean percentage of haemoglobin, however, increases quite regularly with fall in barometric pressure, as was shown by Miss FitzGerald. The importance of increase in the haemoglobin percentage was formerly much exaggerated, at a time when the other more decisive factors in acclimatization were not yet understood, but in the long run, and at very high altitudes, increase of haemoglobin is probably of considerable indirect importance.

Increased Breathing at High Altitudes

I now come to a factor which is certainly of very great importance. Those not familiar with the physiology of respiration and circulation might easily imagine that in order to combat the effects of defective saturation of the arterial blood with oxygen what is chiefly necessary is merely to increase the amount of air breathed, for by this means the pressure of oxygen in the alveolar air and arterial blood can be raised considerably. It is evident also that in persons under greatly reduced atmospheric pressure whether they are acclimatized or not, the breathing is much increased, and more increase in breathing is thus apt to be taken as a sign of acclimatization. But we know now how amazingly delicate is the normal regulation of the hydrogen-ion concentration of the blood, and that this regulation is at once upset with serious effects if, by unnaturally increased breathing, too much carbon dioxide is washed out of the blood. Under the stimulus of want of oxygen the breathing tends to be increased, but this, by washing out carbon dioxide, makes the blood and whole body more alkaline—in other words, produces a state of alkalosis, and since the *normal regulator* of respiration is increase or diminution in the hydrogen-ion concentration round the respiratory centre or centres the increase in breathing from the direct action of want of oxygen is limited, though just at first, before the alkalosis has developed fully, it may be very considerable. The alkalosis also tends to diminish the circulation rate and thus prevent relief which might otherwise be brought by an increase in the circulation rate and consequent rise of oxygen pressure in the tissues.

Although during acclimatization the oxygen pressure of the arterial blood is rising, as already explained, the breathing continues for many days to increase, as shown by the continued fall in the pressure of carbon dioxide in the alveolar air. This increase in breathing cannot, therefore, be due merely to want of oxygen. We followed it closely on Pike's Peak, and in our report attributed it to the gradual development of an acidosis owing to a special action of want of oxygen in stimulating the kidneys to excrete alkali. We had not then realized the alkalosis produced by the slightly increased breathing owing to the stimulus of want of oxygen.

The true facts were revealed in an investigation carried out in steel chambers in London by Kellas, Kennaway, and myself shortly after the war.[9] We found that during the want of oxygen which is immediately produced by exposure to low atmospheric pressure the urine becomes alkaline or much less acid and the amount of ammonia in the urine diminishes greatly, just as in any ordinary alkalosis produced by forced breathing or ingestion of alkali. In other words, the kidneys and formation of ammonia in the body were reacting normally to an alkalosis. The increase in breathing during the process of acclimatization is thus due, not to an acidosis, but to the gradual compensation in a normal manner of an alkalosis produced by the slightly increased breathing caused directly by want of oxygen. As the alkalosis becomes compensated the full effect on the breathing of the slight oxygen want is unmasked more and more, even though the oxygen want itself is continuously diminishing as acclimatization advances. In this connexion I should like to point out that the regulation of the reaction in the body is an active physiological process, and not, as the confused accounts in many textbooks and papers seem to represent, a mere result of the physico-chemical buffering in body fluids, blood corpuscles, etc.

We can thus see why it is that with acclimatization at higher and higher altitudes the breathing during rest is more and more increased, just as in a true acidosis. On Pike's Peak the increase was only about 50 per cent., but on the higher slopes of Mount Everest it would be at least 100 per cent. Graphs constructed by Miss FitzGerald from her observations in connexion with the Pike's Peak expedition in various villages or towns of the Rocky Mountains and elsewhere show the mean decreases in alveolar carbon dioxide pressure and oxygen pressure at different altitudes, together with the increases in haemoglobin percentage. These graphs, which are reproduced in my book on *Respiration*, give us a clear idea of the probable increase in the breathing and haemoglobin during the Mount Everest expedition. But for the tragic death of Dr Kellas from, as appears to have been the case, want of oxygen owing to failure of acclimatization during illness, we should by this time have had full information on the increase of breathing and haemoglobin at great altitudes.

An increase of 100 per cent. in the breathing during rest is noticeable enough, but not uncomfortable. But when the breathing during muscular exertion, such as walking or climbing, is also, as must happen in persons acclimatized at high altitudes, increased by at least 100 per cent., the distress caused becomes very great and at once limits the exertion. I have for long been familiar with this in connexion with observations of the effects of carbon dioxide in mines and submarines and on divers. Owing to a recent discovery by my son, we can now reproduce this phenomenon by causing acidosis in a healthy person breathing ordinary air at sea level.[10] I confess that when he first produced

the acidosis on himself I was almost ashamed to walk with him at a leisurely pace along the streets of Oxford, for he was panting so hard as to attract everyone's attention

We found on Pike's Peak that some part of the greatly increased breathing on considerable exertion was due to the immediate effects of want of oxygen, but comparatively little. Air enriched with oxygen would not give more than very partial relief to the breathing in a person acclimatized to a high altitude, and the benefit might be more than neutralized by the inconvenience caused by the weight of the apparatus. In the case of a person not acclimatized, however, the relief to all the symptoms would be complete if the oxygen was sufficient. He would breathe during exertion just as easily as at sea level, but if he were not acclimatized, and the apparatus failed at an altitude of about 25,000 ft. or even less, he would certainly perish. The cause of death would be a fatal combination of oxygen-want and alkalosis, and the immediate cause would, to judge from our observations in steel chambers, be failure in the depth of breathing.

Acquired Toleration of the Tissues to Low Oxygen Pressure

I now come to a fourth factor in acclimatization. This factor, as it seems to me, has been revealed by the recent Anglo-American expedition to a high altitude in Peru under Mr. Barcroft's leadership.[11] The Peruvian expedition differed from that to Pike's Peak owing to the fact that observations could be made on persons who were natives of the place, or who had been acclimatized for long periods. Owing to improved technique, analyses could now also be made of the gases in arterial blood. The new factor is that persons who have been long acclimatized become able to exist normally with a considerably lowered pressure of oxygen in the arterial blood. Apparently the tissues themselves become acclimatized to the lowered oxygen pressure, and this, of course, diminishes the stimulus to secretion. At any rate numerous individuals were found who were living healthily with their lips and skins of an abnormally bluish tinge, and who became very distinctly pinker when they were moved to a lower altitude or breathed air enriched with oxygen. The haemoglobin of their arterial blood was found to be only about 83 per cent. saturated with oxygen, whereas such a low saturation if it were produced rapidly, as in patients with certain acute lung affections, would be indicative of danger to life.

We are familiar clinically with what appears to be a similar phenomenon, and I have referred to it in my book on *Respiration*. We see persons with chronic emphysema, or certain chronic heart affections, going about and leading a fairly normal life with their lips and skin more or less blue, and there is no doubt that in many of these cases the blueness depends on imperfect saturation of the arterial blood with oxygen, and that the patients in question have become acclimatized to it. This fact has for long obscured the deadly significance of any appreciable degree of arterial cyanosis in ordinary patients who are not gradually acclimatized, and the urgent need, so strongly emphasized recently by Meakins, of combating the cyanosis by continuous enrichment of the inspired air with oxygen or by any other means.

We observed no such cases among acclimatized persons in the Pike's Peak expedition, but this was probably due to the very limited number of persons observed, and the fact that the duration of acclimatization had been so short or the acclimatization so perfect. Had we been able to analyse the arterial blood we should certainly, however, have found a distinct diminution in the normal saturation with oxygen, and a corresponding considerable diminution in the arterial oxygen pressure, for had this not existed the whole of the phenomena would have been quite unintelligible as already pointed out. In the case of Meakins there was after acclimatization in the Peru expedition, a diminution of 4 per cent. in the arterial saturation, and this small difference is just about what we should have expected from the Pike's Peak results.

The Inferences of Mr. Barcroft and Professor Krogh

In his report on the expedition Mr. Barcroft draws what seems to me to be the amazing inference that the blood gas analyses indicated that no active secretion of oxygen exist. I have already given the evidence that it is practically impossible to decide this question directly by means of either aerotonometers or blood gas apparatus, together with a summary of the evidence, both direct and indirect, in favour of the secretion theory. It seems to me that without a shadow of doubt this theory still holds the field completely, though I am sorry to have to differ so emphatically from Mr. Barcroft, to whom physiology owes so much. The secretion theory rests not merely on the direct evidence furnished by the carbon monoxide method, but also on a mass of indirect evidence, part or which I have summarized. The blood gas analyses on members of the Peru expedition seem to me, when these analyses are interpreted in the light of existing knowledge, to afford very strong evidence in favour of the secretion theory, but it is much to be regretted that the carbon monoxide method was not employed. The details of the analyses bear out up to the very hilt, the conclusions of the Pike's Peak expedition. The only observations which at first sight seem to bear out the diffusion theory are the results of determinations by a modified aerotonometer method of the oxygen pressure of arterial blood at sea levels. These results are however, quite inconsistent with the aerotonometer results for animals, and were I am confident, erroneous for reasons which can be surmised easily.

Not only Mr. Barcroft, but also Professor Krogh of Copenhagen has opposed the secretion theory. The time at my disposal prevents me from dealing with the later experimental method relied on by Professor Krogh for determining the rates of diffusion of gases into the blood. This method seems to me fallacious, but the point may be waived for the present. What is essential is that if the measurements are even very approximately correct the aerotonometer results of Frederieq and Krogh are hopelessly inconsistent with the theory that the oxygen pressure of the mixed arterial blood represents the mean oxygen pressure of blood leaving the lung alveoli. While I admire so much of Professor Krogh's work, I think he suffered the misfortune of putting his money on the wrong horse when he definitely opposed the oxygen secretion theory of his former chief, Professor Christian Bohr.

The Mount Everest Expedition of this Year

In the Mount Everest expedition of this year Colonel Norton and Dr. Somervell climbed without oxygen to a height of 28,100 feet, and had slept well at 27,000 feet. But for an affection of Dr. Somervell's throat, and the limited time for return, they could have gone higher, and Colonel Norton actually did climb some distance further up an extremely difficult and dangerous slope. He reports that although the panting on exertion was, of course, very great, he had none of the mental symptoms of serious lack of oxygen. He considers that so far as the physiological difficulties are concerned it is quite possible to get to the top without oxygen, and he doubts whether the advantages of an oxygen apparatus such as that used are sufficient to outweigh the disadvantage.

At 28,100 feet the resting alveolar oxygen pressure would, to judge from Mrs. FitzGerald's graph, be only about 26 millimetres. Arterial blood such a that of the observers on Pike's Peak could even during complete rest only be about half-saturated with oxygen at this pressure apart from secretion of oxygen, and the person to whom it belonged would be black in the face. If considerable alkalosis existed the blood would be more highly saturated, but the alkalosis would in its bad effect counteract the good effects of the increased saturation. It seems to me that with the publication of the Mount Everest results the opposition to the oxygen secretion theory of acclimatization is in a position more hopeless than ever before.

In the Pike's Peak report the author (Douglas, Yandell Henderson, Schneider and myself) expressed the conclusion that though it would be *hopeless* for an unacclimatized person to reach the top of Mount Everest even by aeroplane or balloon without the use of oxygen, there was no known physiological reason why an acclimatized person should not succeed in climbing it. At this point I would like to refer to an unfortunate misunderstanding which arose

crept into a paper (in the *Geographical Journal*, vol lx, p 410, 1922) by the late Mr Mallory He mentioned that he had been told by the Professor of English Literature at Oxford that the physiologists had proved in a pressure-reducing chamber that it was impossible to climb to the top of Mount Everest without oxygen There was evidently some misunderstanding about this statement The experiments referred to were possibly those made on *unacclimatized* persons by Kellas, Kennaway, and myself The Oxford physiologists who have concerned themselves with the subject have never regarded the ascent of Mount Everest as impossible, on physiological grounds, without oxygen, or supposed for a moment that any experiments hitherto made in steel chambers indicated such an impossibility, but it is quite evident that the less complete the acclimatization, the more benefit will be obtained from oxygen In this connexion it would be interesting to try whether acclimatization at the highest camps could not be hastened by administering small doses of an acid salt or of ammonium chloride, so as to get rid of the alkalosis more rapidly than in the natural slow way

The Acclimatization Phenomena as a Whole

When we regard as a whole the phenomena of acclimatization to a low atmospheric pressure we see at once that when acclimatization is complete the organism is still in a physiologically different state from what it was before exposure to the low pressure The breathing is greatly increased, the concentration of the blood in haemoglobin and red corpuscles is also increased, as well as the blood volume, the blood plasma is altered in composition, the blood-forming bone-marrow is increased, and if we could detect them we should probably find histological changes in the lung epithelium All these changes, and probably many more which are not yet discovered, centre, quite evidently, round what may metaphorically be called an attempt to keep the oxygen pressure, and simultaneously the hydrogen-ion concentration, about and within the living tissues constant But the attempt is not completely successful a slight deficiency in both oxygen pressure and hydrogen-ion concentration remains over, and doubtless becomes more appreciable the greater the altitude This deficiency is necessary as the stimulus for maintaining the state of adaptation The primary stimulus is the deficiency in oxygen pressure, and the hydrogen-ion deficiency is secondary to this If we ask why the hydrogen-ion deficiency at least should not be fully compensated, the probable answer is that this would involve such a loss of sodium, and perhaps potassium, as is resisted

Although from its very nature the process of acclimatization cannot be theoretically complete, yet it has the unmistakable effect of keeping the oxygen pressure within the body approximately constant without more than slight disturbance of other important factors in environment The carrying out of this involves both functional and structural changes These changes are intelligible and predictable on the assumption that life tends to assert and maintain structure, activity, and environment in a normal and definitely co-ordinated manner Without this assumption biology is to my mind nothing but a jumble of disconnected and unintelligible observations It was a true physiological sense that led Ludwig and Bohr to suspect the existence of oxygen secretion by the lungs, and that led Claude Bernard to his great generalization about the active maintenance of the constancy of the internal environment The everyday reactions of living organisms to change in environment seem to me not in any way different in kind from the reactions during acclimatization to higher altitudes, and I cannot myself see that physiology is ever likely to get anywhere worth getting to unless it makes the fundamental assumption just referred to

This assumption differentiates it completely from mere applied physics and chemistry Biological reality is something which our present physical and chemical conceptions fail to represent and can never come near representing until they have been profoundly modified This modification may come in the future, but meanwhile biology must regard itself as an independent science It is also an exact science, since it is everywhere dealing with and revealing exact regulation and co-ordination Nothing gives us, perhaps, a clearer and more comprehensive idea of this regulation than thorough study of the phenomena of acclimatization to higher altitudes That study must, however, be based on exact quantitative results and coherent reasoning and it is this paper I have had to point out incoherency in the reasoning of scientific friends who in other directions have made most valuable contributions to physiology, I hope that both you and they will understand that any other course would be inconsistent with scientific honesty on my part

The Vicary Lecture

ON

RICHARD OWEN AS CONSERVATOR.

GIVEN IN THE THEATRE OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, NOVEMBER 12TH, 1924,

BY

SIR ARTHUR KEITH, M.D., F.R.S.,
CONSERVATOR OF THE MUSEUM

(Abstract)

In the Vicary Lecture of last year* I gave an account of the dramatic proceedings which culminated in the confession by Sir Everard Home that he had burnt the Hunterian manuscripts These proceedings were enacted in this College during the summer of 1824—just a century ago The Board of Curators, six members of the Council of the College, to whom the management of the museum was delegated, then met to consider afresh the problem of describing and cataloguing John Hunter's specimens—some 17,000 in number The Board sent for its conservator, William Clift, and told him to proceed with the preparation of catalogues forthwith

William Clift

Let us see how William Clift was situated He was then 50 years of age, *from* Hunter's death in 1793 until the summer of 1824 he had, in reality, been servant to Sir Everard Home, all he knew he had picked up for himself, time after time he had made fruitless attempts under Sir Everard Home to carry out the task just imposed upon him His daily duty of meeting parties at the door of the College and conducting them round the floor-space and galleries of the museum—a single great room, which had been built for the display of Hunter's treasures—was altogether a joyful task *for him* But when it came to stepping into John Hunter's shoes and explaining and interpreting to all the world the harvest of the greatest medical genius of the eighteenth century—a much abler man than the faithful, modest William Clift might well have shrunk back He set to work in his old way pen in hand, and in his finest script copied from such Hunterian documents as he had saved, and from other sources such extracts as these had on the collections made by Owen. The Board met from time to time and examined these extracts but by the end of 1826 it had become apparent to John Abernethy, surgeon to St Bartholomew's Hospital and at this time President of the College that these and those helpful friend William Clift had that hard [illegible] must be given a [illegible]

* See [illegible] which [illegible] there [illegible] Oct 25 [illegible]

The required assistance as we must suppose Abernethy knew, was close at hand. In the autumn of 1826, when cataloguing production was becoming urgent, Mr Richard Owen, having become a member of the College at the age of 22, put up his plate in Cook's Court, Carey Street (within a stone's throw of the museum), to practise his profession—mostly among young lawyers. Little more than two years had elapsed since he had finished his apprenticeship to a surgeon in Lancaster, in which town he was born and bred. One year he had spent in Edinburgh winning the golden opinion of that most enlightened anatomist Dr John Barclay. The second year he spent at St Bartholomew's Abernethy at once took him on as a prosector and found that Barclay's strong letter of recommendation in nowise exaggerated Owen's abilities. From Barclay young Owen had learned to appreciate Hunter as well as the more modern anatomical schools of France represented by Cuvier and Cuvier's rivals—the philosophic anatomists. In Edinburgh Owen had taken the initiative in founding a Hunterian Society. As a student at St Bartholomew's he wrote two papers on surgical subjects—one on a case of aneurysm of the gluteal artery, the other on a case of encysted calculus of the bladder. Taking all these circumstances into account one cannot help thinking that Abernethy had something to do with the selection of the site at which Owen sought to establish himself in practice during the autumn of 1826.

Clift and Owen

When the Board of Curators met in February, 1827, Richard Owen was asked to attend. He was engaged to assist Mr Clift, his emoluments being £30 a quarter, with permission to attend to his practice in the intervals of his duties. Thus William Clift and Richard Owen were brought together—one of the strangest partnerships to be found anywhere in the annals of medicine or science. They were contrasted types. Clift was a small man—only a little over 5 ft., Owen stood 6 ft. in his stocking soles. Years later Carlyle described him as "the tall man with the great glittering eyes" for his eyes were great and full and Clift's were small and sunken. Clift was born of humble people—he was happier as servant than as master. Owen came of a good family—his father was a West Indian merchant who fell on evil times. Owen was born to command, he claimed equality with the best. Clift was the meticulous gatherer of small facts. Owen we shall see, dealt with big things, he could imagine, create, and discover—he was a statesman, he could conceive and execute. But Clift and Owen had this in common—partisanship—they raised common enmities with ease and maintained them with vigour. Thus it came about that Richard Owen was engaged to assist William Clift to prepare catalogues, but in the course of events, as one could have foreseen, it soon came about that the roles were reversed, and later still Owen dispensed with the conservator's assistance altogether.

Leaving these two men to pursue their vocations in the museum throughout the year of Owen's appointment (1827), we turn aside to note certain events which happened outside their daily routine and which had a very important bearing on the history of the museum. The conservator's house looked out on the trees of Lincoln's Inn Fields, its back staircase served the gallery of the museum as well as the conservator's bedrooms. In September 1827, the inmates of this house were the conservator, his wife and their two children—William Home Clift a young man of 26 and Caroline Amelia Clift, aged 25. Young Home Clift was to be his father's successor. His father had trained him in museum ways, and at present he was struggling very ineffectively at the compilation of catalogues. He was light, gay, and fond of company, a source of anxiety to his father. It was otherwise with Caroline, she had inherited her father's slight build of body and could pull his heart-strings as she would. Years afterwards Caroline Fox described her as "a very perfect little fact in the great history of the world."

Caroline Clift

It so happened on a September day in this year that little Caroline mounted some steps to put a bell pull to rights, overbalanced, and fell. Her brother fetched Richard Owen from the museum to render first aid. The tall young surgeon with "the great glittering eyes" speed is proceeded to fall in love with his patient—"the perfect little fact." In a brief wooing by Christmas-time he had presented her with a carved tortoise shell comb, a volume of Cowper's poems and an engagement ring. He was 23 and he was 25. She knew well that she had linked her fortunes with those of a man destined to greatness. This apparently insignificant affair of the bell pull, we can now see, turned out to be a critical event in the history of the museum. It not only gave Richard Owen a perfect wife but it secured for the Hunterian Collection the services of the one man then in England who had the ability and energy to grapple with its problems.

Two years later, although still in practice, Owen was regarded as a permanent member of the museum staff and paid at the rate of £150 a year. But even in 1829 such an income was altogether insufficient to set up house on. Hence early in 1830 we find Owen in Birmingham in search of a house-surgeoncy. From there he wrote a letter to Caroline which permits us to see what kind of man and lover he was. "You know not" he writes, "how rapidly I have succeeded in gaining golden opinions from all sorts of men in this place. You have lent me your attractions and have prompted me in all my interviews." He saw no prospect of an early marriage by settling in Birmingham, his heart, he wrote, longed for the "happy Fields." The true lover at the end of this letter exclaims, "The die is cast, you shall be with me ever and guide and prompt and see my exertions." He returned from Birmingham in this mood, and within twelve months the College was in possession of its first batch of catalogues—for which it had waited wellnigh thirty years.

We find entries in William Clift's private notebook which show us that Owen did not return to his rooms in Cook's Court but became an inmate of the conservator's household. He paid £15 a quarter for board and lodgings and young Clift paid the same. But there was this difference. Owen settled his account promptly on pay day whereas the easy-going Clift was always behindhand and had usually to borrow part of his belated payment to meet present needs. Pitched however, borrowed only when setting out to see his mother in Lancaster—which he did every year, and often had to wait for an advance to bring him back to work. In September, 1832, these entries in William Clift's private notebook suddenly cease. When we turn to his diary we find the explanation. On the evening of this day (September 11th, 1832) a most unfortunate and fatal accident occurred to my dear son, in alighting from a cabriolet near the lower end of Chancery Lane at about 10 o'clock p.m." September 17th "This morning about half-past-three my poor son breathed his last." The cab accident comes into the history of our museum, for it left the ultimate succession to the conservatorship open to Richard Owen.

The amount of work which Owen got through after his return from Birmingham, the researches he carried out and the discoveries he made, leave one in wonderment with the death of William Home Clift in 1832 they became almost incredible. But his Herculean effort did not impress the Board of Curators—for a reason I shall explain presently. In 1833 Owen protested he complained to the Board that he was worse paid than the meanest country apothecary and that he had to carry on his work in a draughty thoroughfare. The Board raised his salary to £200 a year and gave him a more comfortable workplace. In 1834 the museum had to be rebuilt and extended. All the responsibilities of the change fell on Owen. In the following year, 1835 when the building alterations were completed, quarters were provided for Owen, now the assistant conservator, behind the museum with a door opening on Portugal Street on which "Mr Owen" had his name inscribed for he still regarded himself as a surgeon waiting for practice. In this year 1835 his salary was raised to £300 a year, which apparently justified him in embarking on marriage. Early in the morning of his thirty-first birthday July 20th he and Caroline Clift drove to St Pancras Church where they brought an eight years' engagement to an end by a happy marriage and a brief honeymoon. And then back to catalogues! Here however I must note a little but significant entry in William Clift's cashbook. He drew from the bank

500 golden sovereigns at this time, 30 he put in one bag for the bride, 30 in another for the bridegroom, and 440 went to their bank account John Hunter's apprentice was proud of his son-in-law, and well he might be

Cataloguing the Museum

I must now turn back and briefly trace the course of events in the museum from the time Owen was engaged as assistant to the conservator until his marriage From the *minute-books of the Board of Curators* we find an ever-recurring call for catalogues The conservator always responds "coming," but never comes When Owen returned from Birmingham matters rapidly changed—catalogues were prepared in rapid succession In the spring of 1831 six volumes had been written, printed, and published, six sections of John Hunter's collection had at last been supplied with catalogues—namely (1) Morbid specimens in spirits, (2) Morbid specimens in a dried state, (3) Human and comparative osteology, (4) Natural history preparations, (5) Monsters, (6) Vascular and miscellaneous preparations The two largest and most important sections still remained untouched—namely, the physiological series, about four thousand preparations, by which Hunter had sought to illustrate the manner in which the functions of the animal body are carried on in all forms of living things—movement, circulation, respiration, digestion, reproduction, development, and growth Even more difficult to handle was his collection of fossils—enigmas to the men of Hunter's time, but not to him

The Board ordered Owen to prepare a catalogue of the physiological series It was estimated that it would occupy him for three years Part I, which covered the preparations illustrating the modes in which locomotion and digestion were carried out in the animal kingdom, occupied two years While cataloguing this single section of the physiological series Owen found it necessary to dissect two hundred animals in order to identify Hunter's preparations and to complete the founder's formulated design He became *the most active Fellow of the recently founded* Zoological Society, somehow he scraped the money together to become a life member He claimed and obtained the first call on all the animals which died in the gardens of the Zoological Society He gave such vivid and full accounts of his dissections as had never before appeared in England A single example, chosen from scores at our disposal, will serve to illustrate the quality of his genius A member of the College, Mr George Bennett, brought home from the Pacific in 1831, and presented to the museum, a specimen of the pearly nautilus—a "living fossil," almost the first to reach Europe In 1832 the Board entrusted it to Owen and requested him to dissect it and prepare a description for publication He spent *five months on it*, and, although imperfectly preserved, he unravelled its exact structure, and fathomed its relations to all other living cephalopods as well as *the relations of these to one another*, he applied to it Hunter's methods, and noted how its bodily functions had been carried out during life He was his own dissector and his own draughtsman—a *finished workman* in both capacities The monograph was published by the Council at a cost of £365 It drew unstinted praise from every source except that from which Owen had expected most—his own Board Clift thought "Owen was much to be pitied", Sir Anthony Carlisle, a member of the Council of the College, bluntly said that "his pearls had been cast before swine"!

Conflicts with the Board

On reading the minutes of the Board of Curators at this time one is made conscious of a feeling of antagonism between the members of the Board and its servants Clift and Owen—an antagonism which flared up into open strife in 1841 and reached a climax in 1842 *In* the spring of 1841 Owen finished the fifth and last volume of the catalogue of Hunter's physiological series The preparation of this catalogue occupied him ten years, during which time he passed from being an obscure member of his College to being acclaimed the first anatomist of the age" Honours were being showered on him by learned societies at home and abroad The ladder by which he reached greatness was made by Hunter, but it was just because Owen understood Hunter's aim and design and knew how to make the steps secure that success came to him As he proceeded from volume to volume of this catalogue he encountered innumerable problems which required laborious research and uncommon insight for their solution In the ten years spent on it he contributed to learned societies 157 papers—all of them abiding additions to knowledge, many of them opening up great unchartered territories of animal life Besides these he wrote ten volumes in the form of catalogues or treatises Every year, from 1837 onwards, he gave in the theatre of the College twenty-four Hunterian lectures, in which he expounded fresh observations and generalizations gleaned in the course of his work in the museum and in the Zoological Gardens One marvels at what he accomplished, and how he managed to get so much out of his body, his brain, and his purse For the scientific societies to which he belonged were expensive he was fond of society, of the theatre, of music, of dining out, and of famous men Yet his income was his salary of £300 with £50 additional for lectures, for *soon after his marriage* he abandoned all thought of gaining money from practice Caroline Owen must have managed well

In 1839 the Board of Curators was *reconstituted* and became the Museum Committee Three members of this committee require our attention—Mr Robert Keate, *surgeon to St George's*, Mr George James Guthrie, *surgeon* to Westminster Hospital, and Mr John P Vincent, surgeon to St Bartholomew's Their patience with Mr Owen was well-nigh exhausted by 1840 The committee informed *him* that it was dissatisfied with the way he was spending his time, particularly as regards the study of fossils Owen defended the collection and *study of fossils and declared* he worked solely for the credit of the College Mr Darwin had presented to the College the remarkable fossils he had gathered in South America *while* on board the *Beagle*, and Owen had described them "When," asked Mr Guthrie, "had Mr Owen obtained permission to do such a thing" "had Mr Owen obtained permission to do such a thing," Mr Keate, *who* was then president, told him "he must give his full time to the museum or resign" The committee threatened to stop lectures and all forms of research *until* catalogues were completed The painting of a portrait of a chimpanzee, which Owen was having made for the museum, was left on his hands because it had not been sanctioned The attendants in the museum were ordered to report directly to the committee every week, not through their officers Mr Guthrie went into the museum and altered the arrangement of the specimens

The climax came on January 25th, 1842 A special meeting of the Museum Committee, with certain additional representatives from the Council of the College, was summoned to consider *Owen's position* Clift and Owen waited by the door, Owen was called in The president of the College, Mr Guthrie, informed him that there was grave dissatisfaction in the Council concerning the manner in which he performed his duties Owen expressed his regret if he had given cause for offence and was conciliatory He was then asked if he would take over the duties of conservator with the proviso that he would publish nothing without having first obtained the permission of the Council Owen expressed his willingness *to take over the duties of conservator* with one exception—namely, the daily task of conducting parties round the museum This difficulty was overcome, William Clift, *who was to become* senior conservator, wished to retain the conduct of parties Poor William Clift was merely a spectator in these proceedings He was given £400 a year for life He vacated the conservator's official residence and his *son-in-law* moved into it And here we must leave Owen as he enters the second period of his conservatorship, it was to last fourteen years—until 1856, when he *became* superintendent of the Natural History Department of the British Museum Suffice it to say that it was even busier more brilliant, and *more turbulent* than *his first period*

Clash of Ideals

What was the cause of these conflicts between Owen and his committee? He was proud, imperious, overbearing and, it must be owned selfish and jealous, especially towards his rivals and juniors His committee may be accused of short-sightedness Although the opposing qualities may be

contributed to the quarrel, yet the real cause of the conflict lies elsewhere The truth is that Owen had yoked John Hunter's chariot to Cuvier's steeds and his committee if it did not know exactly what had happened did see that the chariot was moving in a wrong direction as far as surgery and medicine were concerned Hunter pursued his studies and built up his museum to throw light on man—on the nature of his disorders and diseases, and on the manner in which the functions and actions of his body are accomplished He knew well that the collections he had assembled might be employed for two other purposes His dissections might be used, not for the study of function, but for the classification of all living things into natural groups and orders He knew that his great collections of fossils opened vistas into past ages of the world John Hunter turned his back on such aims but two years after his death Cuvier set to work He built up anatomical collections just for the two purposes which Hunter refused to entertain, and by his genius and industry enthralled the world by his discoveries during the first three decades of the nineteenth century At first Owen's sympathies were with Hunter's original aims but they soon became dissipated under the brilliance of Cuvier's sun When Cuvier visited our museum in 1830, two years before his death he fired young Owen with his aims and zeal We must remember that in Owen's time the Natural History Departments of the British Museum were in abeyance and Owen set out to make our museum supply a national deficiency He intended to make it the home for the classification of all forms of animal life—for the separation of the animal kingdom into natural groups according to structure More particularly he intended that the museum should become the headquarters for the interpretation of past worlds of life If we are to understand the continual friction recorded in our minutes throughout Owen's time we have to keep in mind the clash of ideals—the ideal the Museum Committee had in view and the ideal which Owen nursed as if it were his religion The committee was for ever trying to get Owen to go its way and he was for ever breaking off to follow his own path It was in Cuvier's world that Owen lived, not John Hunter's If we are to study structure and function as a service to medicine we must go back to Hunter"

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, BRADFORD, 1924

SECTION OF PATHOLOGY AND BACTERIOLOGY

Professor C H Browning, M D, President

XANTHOMA AND XANTHOSIS

BY

MATTHEW J STEWART, M B, F R C P,

Professor of Pathology University of Leeds

The importance of the part played by cholesterin and its esters in pathological processes is receiving increasing recognition, an outcome of the large amount of work—anatomical, chemical, and experimental—which has been done on this subject in the last twenty years The purpose of the present communication is to integrate a number of different pathological states in which the deposition of cholesterin fat is the salient anatomical feature and to show at the same time how frequent is the occurrence of minor grades of this condition in relation to a large series of pathological processes

When cholesterin fat is deposited in a cell in crystalline form it causes the cytoplasm to assume a "foamy" appearance in paraffin sections while a sufficient aggregation of such cells gives rise to an area opaquely yellow to the naked eye The gross and microscopic appearances are exemplified normally by the outer two-thirds of the adrenal cortex and in the female by the corpus luteum, especially the corpus luteum of pregnancy in its later stages Pathologically, foamy cells are, in the main, phagocytic cells of endothelial origin, but there is evidence to show that fibroblasts may become similarly affected, and in the central nervous system a corresponding part is played by the neuroglia

In a previous communication[1] I have classified local cholesterin fat deposits into those which are due solely or principally to local tissue changes and those which are the focal expression of a condition of hypercholesterinaemia The latter group is much the smaller, its principal constituents being the various forms of cutaneous xanthoma the "strawberry gall bladder" cholesteatomata of the choroid plexus, and probably certain cases of arterial atheroma The former group includes a large number of local necrotic and chronic inflammatory lesions of various kinds, and, especially conditions in which there is retention in the tissues of lipoid rich secretions or transudations, and exudations A third group might be added lesions in which the deposit of cholesterin fat is merely the continuation of a normal function of the cells or the part—for example, adenoma of the adrenal cortex

The extracellular deposition of crystals of pure or nearly pure cholesterin in many of these lesions and the frequent occurrence of foreign body giant cells in relation thereto is described in detail in the paper referred to above Suffice it to say here that the condition is usually associated with some form of cellular death, and especially with lesion in which large aggregations of foamy cells are themselves becoming or have already become, disintegrated Thus I found that whereas small early cholesteatomata of the choroid plexus are composed simply of closely packed aggregations of foamy cells in the meshes of a delicate connective-tissue stroma, the corresponding tumours of larger size are mere encapsuled collections of cholesterin plates with or without related foreign body giant cells

A short account may now be given of some of the more important examples of cholesterin fat deposit

A Hypercholesterinaemic Xanthosis

1 *Xanthoma*

This is a cutaneous disorder in which one or more bright yellow plaques or nodules make their appearance on various parts of the body Several clinical varieties are recognized according to the site, character, and etiology of the lesion When it is confined to the eyelids—and this is much the most common form—it is termed 'xanthoma palpebrarum", when it is more widely disseminated 'xanthoma multiplex" Sometimes the lesions are flat (xanthoma planum), sometimes nodular (xanthoma tuberosum) In a small proportion of cases usually of multiplex type, there is an underlying diabetes—hence xanthoma diabeticorum The essential lesion is the same in all—the accumulation in the subepithelial layers of the skin of numerous phagocytic cells laden with esters of cholesterin These cells are present in great profusion as a rule, and to begin with are most abundant around the smaller blood vessels In lesions of longer standing especially those of tuberose type there is also much proliferation of fibrous tissue which leads ultimately to a relative reduction in the number of foamy cells, as well as to diminished vascularity

The presence of giant cells in cutaneous xanthoma has often been noted For the most part these are giant foam cells in which the nuclei numbering from two to twelve or so are situated centrally, and the peripheral cytoplasm is exactly similar to that of the uninucleated form Occasionally giant cell of the ordinary foreign body type is seen deeply eosin staining non foamy cytoplasm and large nuclei more widely scattered nuclei are seen These are more frequent in xanthomas of large size and long standing and are often related as above described to extracellular crystals of pure or nearly pure cholesterin which have been formed by disintegration of the foamy cells If there is evidence to show that such cells pass through a foamy giant-cell stage

Cutaneous xanthoma especially the multiple nodular type is sometimes accompanied by similar lesions affecting

tendons and tendon sheaths and the capsules of joints These lesions should be clearly distinguished from the myeloid tumour of tendon sheaths, to which they bear superficially a close resemblance The latter is a strictly local affection, always single, and occurring chiefly on the fingers and hands, true xanthomatous tumours are frequently multiple, are often associated with cutaneous lesions, and occur most commonly in the tendo Achillis and the tendo patellae The case recently reported by Ollerenshaw (1923)[2] is apparently of this kind Microscopically the *myeloid tumour of tendon sheaths is a fibro-endothelioma, with numerous osteoclast-like giant cells uniformly distributed throughout it, and either with or without local patches of* xanthosis The other *is essentially xanthomatous, with occasional foamy giant cells, or foreign-body giant cells related to cholesterin plates*

The association of cutaneous xanthoma with an increased cholesterin content of the blood was first reported by Chauffard and Laroche (1910),[3] who found it in two of the four cases which they examined Many records by various observers are now available, *and have recently been reviewed* by Harrison and Whitfield (1923) [4] In the great majority some degree of hypercholesterinaemia was present at the time of examination, and there are good grounds for supposing that even in those which gave a low figure a state of hypercholesterinaemia had existed at the time of onset of the cutaneous lesion Cases are on record, for example, where xanthomas have continued to exist long after the hypercholesterinaemia which produced them had disappeared This is due to the chronic inflammatory thickening and fibrosis *which have taken place, resulting in* greatly *reduced* vascularity, and consequent interference with the reabsorption of the lipoid In xanthoma diabeticorum, on the other hand, the skin lesions, especially if small, sometimes disappear *quite* rapidly This is due to two factors, as Major (1924)[5] has *emphasized* a disappearance of *lipaemia* and hypercholesterinaemia on the one hand, and the presence of a good blood supply to the skin lesions on the other

The *normal cholesterin content of the blood plasma* is *given* by Chauffard, Laroche, and *Grigaut (1911)*[6] *as varying from 0 11 to 0 18 per cent In a series of twelve* normal individuals investigated by Dr Cecilia Shaikin (1922)[7] in my laboratory (by a modification of Myers and Wardell's colorimetric method) the figures for blood plasma ranged from 0 13 to 0 19 per cent In xanthoma the highest readings are given by diabetic cases, and higher figures are obtained in xanthoma multiplex than in xanthoma palpebrarum In a series of six cases of xanthoma palpebrarum which we have examined* the figures ranged from 0 124 to 0 4 per cent, and in four they were *distinctly above the* normal maximum *In a case of xanthoma diabeticorum* now under observation two analyses at an interval of ten days gave the extraordinarily high figures of 3 8 and 4 2 per cent In two similar cases reported by Hoffmann (1918)[8] the blood cholesterin was 2 5 per cent, and in Kahn's (1920)[9] case it was 1 4 per cent In published cases of xanthoma multiplex and xanthoma tuberosum other than diabetic, figures ranging *from* 0 4 to 0 7 per cent are not *uncommon*

It is generally supposed, *then that cutaneous xanthoma is the result of a focal outpouring of cholesterin fat from* the overcharged blood into the superficial layers of the corium, where it is speedily taken up by mononuclear (endothelial) phagocytes Local trauma is of some importance in determining the onset of the lesion, as is well seen in a case recently reported by Major (1924)[5] A diabetic of 16 (blood sugar 0 322 per cent, cholesterin 0 4 per cent) was bitten at two places *on the forearm* by a mosquito Two small inflammatory nodules were produced, and a few days later a deposit of yellowish-orange pigment appeared The nodules became quite hard, and presented the typical appearance of the lesions of xanthoma diabeticorum They cleared up promptly under insulin treatment

The *disturbances of cholesterin metabolism which lead* to the *formation* of xanthoma are *beyond the* scope of the present paper, but reference may be made to the recent review of the subject by Harrison and Whitfield (1923) [4]

It is obvious from what has been said that xanthoma is quite definitely a non-neoplastic disease, and the term is therefore strictly a misnomer The condition is one of cellular reaction to the presence of a definite chemical substance, and when this stimulus is removed the tendency is for the lesions to regress, certainly they cease to grow Nor is there histological evidence of actual proliferation of xanthoma cells once formed Indeed, there are good grounds for believing that this is an effete cell which has gone beyond the possibility of recovery of the powers of *proliferation Xanthoma, on the other hand, is a quite* convenient term, belonging as it does to the same category as tuberculoma, haematoma, and syphiloma, and one hesitates to suggest its replacement by "cutaneous xanthosis"

2 *The Strawberry Gall Bladder*

This peculiar and characteristic lesion was *first described* by Moynihan in 1909[10] as "a condition of the gall bladder in which fine grains of calculous material are embedded in the mucosa"—a description by no means wide of the mark although based on naked-eye examination only The cholesterin-fatty nature of the deposit was confirmed microscopically by the writer in 1915 (unpublished observation), and since then a large number of specimens of this kind have been examined *histologically* The term "strawberry gall bladder" was first used by *MacCarty* in 1910,[11] and *is an excellent descriptive name for a definite pathological* entity In the first instance this author wrongly attributed *the appearance to erosion of the spaces at the villi, with replacement of the epithelium by scar tissue* In a subsequent paper on *papilloma* of the gall bladder (1915)[12] he refers to fat-containing cells in the stroma, and later still (1919)[13] speaks of the strawberry gall bladder as due to the presence of a lipoid substance *within the swollen connective tissue* cells which lie just beneath the epithelium A very full description of the lesion has been given by Boyd (1923) [14]

The cholesterin-fat deposit of the strawberry gall bladder is present in greatest abundance superficially—that is, in the tips of the mucosal folds It is mainly contained in groups of foamy cells indistinguishable from those of cutaneous xanthoma, and the peculiar "strawberry" appearance *seen by the naked* eye is due to its irregular *distribution in streaks and patches* A closely related *condition which may* accompany the other or may occur independently is that of lipoid polyposis Here the large amount of deposited cholesterin has led to the formation of polypi, bright yellow bodies of irregular shape, which usually measure from 1 to 3 mm in diameter, and which are often attached to the mucosa by an extremely slender pedicle In several instances I have seen these polypi broken off and lying free in the lumen of the gall bladder Microscopically they consist of solid masses of foamy cells enclosed in the meshes of a thin and delicate *fibrous stroma*, with or without a covering *layer of epithelium* Obviously, lipoid polyposis is merely a *further development* of the strawberry gall bladder, but inasmuch as polypi may be present without any general lipoid stippling, I would suggest that they are more permanent formations which remain behind when the general lipoid deposit is absorbed The lack of vascularity and slenderness of the pedicle would account for this An important practical point is the possible relationship of these conditions, and especially of lipoid polyposis, to gall-stone *formation* The strawberry gall bladder may or may *not be* accompanied by gall stones and when it is, the latter may be of two types—either the solitary *cholesterin* stone, or multiple mulberry calculi, also mainly composed of cholesterin The mulberry stones are usually few in number, *and those of* smaller size bear a remarkably close resemblance to the *lipoid contents* of polypi above described *It seems highly probable* that there is here a direct *etiological relationship*, as Chauffard (1922)[15] *suggests*, and the experimental work of Dyer (1916)[16] may be regarded as affording support for such a view

I am not aware that there are any records of the cholesterin content of the blood in these cases, but from

* I am indebted to Dr Dorothy Priestly and Dr Cecilia Shaikin for the estimations.

post-mortem room experience and other collateral evidence I think there can be little doubt that the strawberry gall bladder is only another local manifestation of the hypercholesterinaemic state Whether the cholesterin fat is excreted directly from the blood into the gall bladder mucosa as in cutaneous xanthoma, or whether as Aschoff and Lacmeister (1909)[1] suggest, it is reabsorbed from an overcharged bile, is still undetermined although the latter seems, *a priori*, much the more likely event The amount of cholesterin fat in the mucosa of the strawberry gall bladder may be very large in six examples investigated by Boyd it varied from 34 to 60 per cent of the dry weight as compared with 0 5 and 1 5 per cent in normal controls

3 *Cholesteatoma of the Choroid Plexus*

This is another form of local xanthosis which is probably the direct result of hypercholesterinaemia The lesion consists of a number of yellow nodules of various sizes usually small, irregularly scattered throughout the choroid plexuses, especially of the lateral ventricles Microscopically they consist merely of a close aggregation of foamy cells within the interstices of a delicate fibrous stroma In cholesteatomas of larger size and longer standing such as occur rarely in man though commonly in the horse (Rous 1912)[18] the occurrence of necrotic changes with cell disintegration leads to extracellular deposition in great abundance of crystals of pure cholesterin These in turn stimulate the production of foreign body giant cells so that the histological picture comes to be entirely different from that seen in the first instance In the cases of cholesteatoma of the choroid plexus which I have examined the lesions have almost invariably been symmetrical and this, together with the state of the suprarenal leads me to the view that here again we are dealing with the local expression of a hypercholesterinaemic state †

4 *Arterial Atheroma*

The yellow colour of the early flat patches of arterial atheroma is largely due to the presence of cholesterin fat in the intima Often it can be seen to be contained within foamy cells but as the patch becomes thickened necrosis and disintegration take place the lipoid becomes largely de esterized, and crystals of pure cholesterin are deposited In man the relationship between hypercholesterinaemia and atheroma is uncertain Experimentally Anitschkow (1913)[19] and others have produced a condition of atheroma in rabbits by overfeeding with cholesterin or cholesterin rich foods, and the collateral lesions met with in some human cases of atheroma point to the presence of a hypercholesterinaemic factor

B XANTHOSIS FROM LOCAL TISSUE CHANGES

1 *The Hyelin Kidney*

In a certain proportion of cases of subacute glomerulo-tubular nephritis deposits of cholesterin fat make their appearance in the cortex especially that part which borders on the medullary pyramids In the earlier stages the lipoid is contained within the epithelial cells of the convoluted tubules, but later, presumably when these cells disintegrate, it is taken up by phagocytic cells in the stroma The naked-eye appearance is highly characteristic at the line of junction of cortex and medulla there is a broad, irregular, streaky zone of yellow colour and opaque aspect, often extending well out into the cortex Microscopically there are groups of foamy cells irregularly scattered throughout the stroma of the cortex, especially its inner half with of course, the characteristic changes of subacute nephritis as well It has been suggested (McNee, 1922)[9] that this unusual lipoid change is due to the damage to the tubular epithelium being of more severe degree than is usual in glomerulo-tubular nephritis Ordinarily it is neutral (glyceryl) fat which is deposited in these cases but when the cells are damaged beyond repair lipoid degeneration takes place

† Cholesteatomata in other situations—middle ear breast brain etc—are of course entirely different from those of the choroid plexuses The latter are the typical 'onion knot' tumours of squamous epithelial origin and almost their only point of similarity to the other is that here also cholesterin plates become deposited in large number a direct derivative of the keratinized epithelial cells

2 *The Myeloid Tumours of Tendon Sheaths*

This is a slowly growing simple tumour most frequently met with on the fingers and hand Microscopically it has the character of an endothelioma (Stewart and Flint 1917) but it also contains numerous giant cells of osteoclast type Large quantities of haemosiderin are liable to become deposited giving a rich brown colour to the affected area and very often patches of local lipoid deposit also make their appearance The latter are of a bright yellow colour to the naked eye, and are composed microscopically of aggregations of foamy cells

It has been suggested by Fleisig (1913)[3] that this is a granulomatous lesion and not a tumour but from the fact that it is xanthomatous in nature My own view is that it is a true tumour an endothelioma and that the deposition of cholesterin fat in certain parts is a purely local phenomenon dependent on local tissue disintegration The xanthomatous nodules occasionally met with in tendon and tendon sheaths should be clearly differentiated (*vide antea*)

3 *Subacute Inflammation of Adipose Tissue*

When adipose tissue is involved in a subacute inflammatory process it is not uncommon for aggregations of large foamy endothelial cells to make their appearance in the interstices of the tissue between the oil droplets Like *foamy cells do here they are filled with cholesterin fat* and often they may be seen going on to the formation of foamy giant cells Rarely pure cholesterin crystallizes out and a remarkable histological picture results in which foamy cells giant cells cholesterin clefts and foci of necrosis are mixed up together Similar changes may be met with in the quieter forms of fat necrosis

4 *Subacute and Chronic Salpingitis*

Even in the early stages of subacute salpingitis while the epithelium is still intact foamy cells may be present in the mucosa in large numbers Later when the pus tube has become lined by granulation tissue and the epithelium has completely disappeared they may be present in the greatest profusion in the inner layers of the wall which they assume in consequence a bright yellow colour The appearances clearly indicate that this lipoid is absorbed from the inspissating pus retained within the tube by closure of the ostium Later pure cholesterin crystallizes out *in situ*, with formation of numerous clefts and giant cells

5 *Subacute and Chronic Abscesses*

These occur in many situations, notably in the liver and kidney, and may show a similar thick yellow wall with innumerable foamy cells in microscopic section I have seen this in portal pyaemia following appendix abscess or low-virulence in chronic pyonephrosis in suppurating papillary kidney in suppurating gumma and many other conditions Often the contained pus is sterile and inspissated and may itself be the seat of crystallization out of cholesterin

6 *Retention Lesions of the Breast*

These have been described in some detail in two previous papers (Stewart 1914[17] and Stewart and Forman 1920[4]) Briefly it may be stated that in certain breast lesions associated with duct obstruction and the retention of secretory and other products a great local concentration of cholesterin fat takes place with the usual cellular response In the earlier lesions even while the dilated ducts are still lined by epithelium the lumen comes to be occupied it may be completely by large numbers of typical foam cells The appearance presented sometimes suggests that the duct epithelium itself is undergoing foamy change but if so the end result is a cell indistinguishable from the ordinary foamy cell of mesoblastic origin In more advanced lesions the epithelial lining of the dilated ducts becomes replaced by granulation tissue in which foam cells are present in large numbers Giant cells also make their appearance either in relation to deposited lipoid plates or in the form of rosettes around branches of the circulatory cholesterin The lesions in which these changes chiefly occur are subacute mastitis and abscess Some

infrequently the patients are multiparae in whom maldevelopment or recession of the nipple has led to non-use of the affected breast

7 *Cerebral Softening, etc*

The lipoid-containing phagocyte or compound granular corpuscle is a prominent feature of all lesions of the central nervous system in which disintegration of myelin is taking place They are seen in greatest profusion at a certain stage of cerebral softening, and account for the bright yellow colour of the wall which, in the course of a few weeks, comes to surround the focus of liquefaction From the local lesion they pass to the perivascular lymph spaces, especially those of the veins While it is probably true that most of these cells are of endothelial origin, like foamy cells elsewhere, there is evidence that some at least are derived from neuroglia, others possibly from fibroblasts (Buzzard and Greenfield, 1921[24])

8 *Dermoid Cysts*

When dermoid cysts lose their epithelial lining, whether from increase in size or from inflammatory or degenerative changes, the exposed connective tissue wall tends to become covered by a layer of granulation tissue in which foamy cells and giant cells are a prominent feature The former owe their presence to absorption of cholesterin fat from the sebaceous and other epidermic contents of the cyst, the latter to unabsorbable keratinous debris, plate cholesterin, hairs, and the like (Stewart, 1913[25]) Rarely, foamy cells are present in such profusion that yellow nodules are formed whose structure is almost indistinguishable from that of cutaneous xanthoma

9 *Mycosis Fungoides*

In the only example of this disease in which I have had the opportunity of making a *post-mortem* examination, a remarkable change was observed to occur in connexion with *the cutaneous tumours of the final stage* The well known phenomenon of disappearance of tumours was a prominent feature in this case Large sarcoma-like skin nodules as *big as a hen's egg would disappear*, without ulceration, in the course of a few weeks, leaving behind areas of mixed yellowish and brownish pigmentation Microscopically the latter was found to be due to the presence of patches of haemosiderin in the subepithelial layers of the skin, the former to a broad zone of foamy-cell accumulation in the cutis vera Here and there narrow strands of closely aggregated small round cells could be seen, relics of the original tumour It would appear that rapid cellular disintegration had taken place, *with absorption of most of the* degradation products, but retention *in situ* of the lipoid and haemosiderin

10 *Lesions of the Thyroid*

In many necrotic, neoplastic, and subacute inflammatory lesions of the thyroid foamy cells appear in large numbers, both within the glandular acini and in the stroma Frequently the process goes on to the deposition of plate cholesterin, with or without foreign body giant-cell reaction The process is a strictly local one, the result of tissue disintegration

11 *Tumours*

The occurrence of cholesterin and other crystals in tumours has been carefully studied by Powell White, 1909,[26] to whose paper reference should be made With the exception of the myeloid tumour of tendon sheaths above referred to, however, it is unusual for a xanthic reaction of the ordinary type to occur Either the crystals are contained within the tumour cells, or they are embedded in necrotic debris so that no cytological response is possible

Summary

A number of lesions of various kinds are grouped together on account of the common characteristic of cholesterin fat deposition In the first group are placed those in which the phenomenon is regarded as the local expression of a condition of *hypercholesterinaemia*—namely, cutaneous xanthoma strawberry gall bladder cholesteatoma of the choroid plexus, and arterial atheroma The second group includes a long list of local lesions, necrotic, inflammatory, and neoplastic, in which the xanthosis is the result of absorption from disintegrating tissues or exudates

IMPROVED METHODS OF OBTAINING CULTURES FROM THE COLON A "SIGMOID LEICH"

BY

CUTHBERT DUKES, O B E, M D, M Sc, D P H

The customary bacteriological methods of examining the faeces in cases of *inflammatory diseases of the intestine* need some improvement Most of the pathogenic intestinal bacilli for which the bacteriologist searches, such as the typhoid, paratyphoid, and dysentery bacilli, are non fermenters of lactose, yet to detect them the faeces are plated out on nutrient media containing lactose, a carbohydrate of *no value to the bacteria sought*, but a readily available source of energy to the unwanted lactose fermenters Consequently such methods yield a plentiful growth of non *pathogenic* lactose fermenters such as *B coli*, whilst the pathogenic non lactose fermenters are notoriously difficult to cultivate An ideal medium would be one which *promoted* the growth of pathogens and inhibited the harmless, this remains to be discovered In the meantime it is better to employ a medium which at any rate gives an equal chance to all

Another reason why the customary methods are open to criticism is because the sampling accepts the host of microbes in the faeces without discrimination, so that the task remains to separate significant bacteria from the multitude of insignificant When disease of the *intestines* exists it is plain that the investigator is more likely to discover the disease-producing germs if he obtains his specimen from the lesion than at a considerable distance In a case of diphtheria of the throat better chances of discovering diphtheria bacilli are offered when the throat is swabbed than would be by an examination of *the sputum*, similarly, in a case of dysentery more success attends the scraping of an intestinal ulcer than the examination of a mass of faeces The vast majority of the microbes to be *found in the faeces of a patient suffering from an intestinal* infection have nothing to do with the disease We should aim at reaching merely the infected area and *avoiding* this massive admixture with saprophytic germs

In looking for better methods for cultivating the pathogenic bacteria of such intestinal diseases as chronic ulcerative colitis and mucous colitis I elaborated the following improved technique The two principles on which this is based are (1) that the cultures should *if possible*, be made direct from the inflamed area and not from the faeces, and (2) the media used should be such as will support the most delicate bacteria with which we are familiar I use a special piece of apparatus which I have designed and which is very simple in working It consists of a glass bottle from which air can be exhausted by a hand pump or water pump it is convenient to have a vacuum gauge fitted to the bottle to record the reduced pressure Attached to the bottle by *stout* rubber connexions is a piece of glass tubing 12 to 18 inches long, the extremity of which is blown into a little cup which will accommodate a plug of cotton-wool The patient is sigmoidoscoped and the

mucous membrane of the rectum and sigmoid carefully examined If an inflamed area or patch of ulceration is observed the cultures are taken from this in the following way A moist plug of sterile cotton wool is placed in the cup at the end of the glass tubing and the long line of glass is passed up the sigmoidoscope till the cup, with its contained cotton wool plug, is pressed on to the region to be examined The tap of the aspirating bottle is then turned and gentle suction exerted for two minutes The secretions and bacteria which are in the mucous membrane are sucked into the plug of cotton-wool, through the sigmoidoscope this can be seen to become coloured red if the patch of intestine is hyperaemic or ulcerated I use a pressure of 20 centimetres on the gauge during the suction After two minutes the "leech" is removed, the cotton-wool plug taken from the glass cup with sterile forceps and dropped into a waiting tube of nutrient broth The 'leech" may be applied to several places, being charged each time with a fresh cotton-wool plug

For the cultivation of the bacteria which have been sucked by the "leech" from the ulcerated areas I use media such as serum agar, blood agar, or ascitic fluid agar It is best to squeeze out the bacteria from the cotton-wool plug with a sterile glass rod which is pushed into the tube of broth and presses the cotton-wool plug against the bottom of the test tube From this tube of broth streak cultures are made at once on to the solid media The incubated plates yield a surprisingly small number of such common intestinal microbes as *B coli*, they bring to light many types of bacteria not often met with in cultures of the faeces It is beyond the scope of this paper to discuss the bacteriology of chronic inflammatory diseases of the large intestine which still await a clearer definition My object is simply to report this improved technique which I have found useful in my work at St Mark's Hospital in the hope that it may be helpful to others The chief advantage this method possesses is that it provides an opportunity for the study of the bacteria living in the diseased patches of intestine without gross admixture with the unwanted population of the lumen of the gut

THE SPREAD AND INCIDENCE OF PROTOZOAL INFECTIONS IN THE POPULATION OF THIS COUNTRY

BY

A MALINS SMITH

In this paper are presented some of the main results of investigations on the intestinal protozoa of the inhabitants of Great Britain, investigations which were carried out at the Liverpool School of Tropical Medicine in the years 1916 to 1919 These results have already been published[1-4] and have also been summarized by Dobell[5] with other investigations of a similar nature They are presented here because of their significance for public health workers and for clinicians, and because they have not yet received such wide dissemination as their importance deserves

The Position in 1916

In 1916 it was believed that *Entamoeba histolytica* was a parasite of man in the tropics and subtropics and that it was absent from Great Britain and most temperate countries, that amoebic dysentery was a disease of tropical regions caused by this pathogenic amoeba and that it was amenable to treatment by emetine which had in fact a remarkably specific curative action upon it It was known that in tropical countries the intestine of man was inhabited by other protozoa belonging to the classes Rhizopoda and Mastigophora About the pathogenicity or otherwise of these, various opinions were held but it was widely believed that one other—*Giardia* (*Lamblia*) *intestinalis*—was harmful At that time no work had been done upon the occurrence of these other protozoa in the population of Great Britain There was very little information as to the incidence of amoebic dysentery in any country and there existed no statistics of the percentage of cases due to *E histolytica* in any outbreak of dysentery Medical opinion was to the effect that the almost complete absence of amoebic dysentery from this country implied the absence of the causal parasite In consequence, if any person in this country suffered from amoebic dysentery or was found to pass *E histolytica* cysts in his stools, some residence abroad, or some contact with persons who had been resident abroad, was immediately postulated

Entamoeba histolytica found in Healthy Youths never out of England

The first step in the investigations which have so profoundly modified this outlook as far as this country is concerned was taken when the stools of a number of healthy recruits in training at a camp in the vicinity of Liverpool were examined microscopically for protozoa These youths were 18 years of age and had never been out of this country The cysts of *E histolytica* were found in a number of the stools, and there was no doubt that these cysts were morphologically indistinguishable from the cysts passed by people who had resided abroad The recruits were all healthy, with no symptoms of dysentery, and it remained to test the pathogenicity of the *E histolytica* they were carrying Four kittens were fed on milk contaminated by the faeces of four of the cases

A few amoebae were found in the faeces of one of the animals six days after the infective feed on the twelfth day symptoms of acute dysentery developed the animal passing mucus blood epithelium and many amoebae Acute dysenteric symptoms persisted to the death of the animal which occurred on the twenty-third day During the whole of this time large numbers of amoebae were passed with the faeces Neither in the fresh nor in stained preparation could these be distinguished from those found in the stools of human beings suffering from acute amoebic dysentery On *post mortem* examination of the kitten a large portion of the mucosa of the large intestine appeared to be superficially necrosed In scrapings enormous numbers of amoebae were found Scattered throughout the large intestine were small discrete ulcers Bacteriological examination of the faeces of the case on which the kitten was fed and also of the kitten itself during the period of acute dysentery and of a scraping of the large intestine were made by Professor Glynn No bacilli of the dysenteric group were found

Thus the youth in question was proved to be a healthy carrier of *E histolytica* in the same sense as are 'contact carriers" from the tropics

Entamoeba histolytica found in all Sections of the Population of Great Britain

Other sections of the population were afterwards examined and infections with *E histolytica* were found in members of every one of these The other intestinal protozoa were also found in all the groups In all 1 093 army recruits 459 adult civilians in hospital, 548 children under 12 in hospital and 207 asylum patients (Whittingham) were examined Not one member of these groups had ever been out of England In addition 504 asylum patients from another asylum (Rainhill) 470 of whom had never been abroad, were examined The percentage of *F histolytica* carriers in these groups, as found by only one examination per case, was

Army recruits	5.6
Adult civilians	1.5
Children	1.3
Whittingham Asylum	9.7
Rainhill Asylum	4.2

Thus in every section of the population, including all ages and both sexes these infections were found This work establishing the wide occurrence of *E histolytica* in the home population, has altered fundamentally the point of view of any person dealing with a case of dysentery or of *F histolytica* infection in this country Since it is almost certain that such a frequent and widespread parasite has not recently established itself in this country it is no longer necessary to presume foreign origin for any home case of amoebic dysentery or for any infection with *F histolytica*

Earliest Age of Infection

The investigations among the children had aspects of further interest It was established that an infection with *E histolytica* had been acquired by a child in the third year of her life and infections with *F coli* and *Giardia intestinalis* had been acquired in the second year of life Later Miss Nutt at Leeds and Sheffield found infections of *Giardia* in a child of 3 weeks and in others of 3 months, 9 months, 11 months, and 12 months respectively

Spread of the Infections

As regards the spread of the infections further investigations were made in connexion with some of the cases of children who were positive for *E. histolytica*, and it was found that the families from which they came were much more highly infected than the average population. The findings for one of these families are given:

Protozoa Found	Parents		Children					
	J. S.	L. S.	L. S.	F. S.	Ja. S.	J. S.	M. S.	D. S.
Entamoeba histolytica	+	+	+	+	+		+	+
E. coli		+	+	+	+	+	+	
Endolimax nana	+	+	+	+	+		+	+
Giardia intestinalis							+	+
Chilomastix mesnili						+		
Ages	41	41	16	13	11	9	7	3

Thus in this one family only there were almost as many *E. histolytica* infections as were found in the 548 cases taken from single members of different families. Such families therefore form, in all probability, isolated pockets among a general population fairly free from infection. Further speculation as to the spread of these infections would perhaps be unprofitable.

Acute Amoebic Dysentery in this Country

Since indigenous infections had been shown to be not infrequent, the question arose whether indigenous cases of acute amoebic dysentery occurred in this country. If they did, probably the place in which they were likely to be found was in a mental asylum, where outbreaks of dysentery still occurred. Accordingly an outbreak of dysentery at Rainhill Asylum was investigated, and there were found among 60 cases of acute dysentery 3 with pathogenic entamoebae in the stools. Two of these patients had never been out of England. All three were much improved by the administration of emetine, and all completely recovered. It was thus shown by microscopic examination that indigenous cases of acute amoebic dysentery do occur in this country, though it still remains almost certain that the great majority of the cases in this outbreak were bacillary in origin.

Conveyance of Entamoeba histolytica from One Person to Another

The method of conveyance of the parasite from one person to another is clear in so far as we know that *E. histolytica* must be conveyed by contamination of food or drink with fresh faecal matter containing the cysts. The amoebae are very short-lived and cannot spread the infection. Even the cysts cannot withstand drying nor live long outside the human body. In the case of other similar diseases the suspicion of acting as carriers often falls upon domestic or other animals accompanying man. In this disease, however, there is no evidence of the intervention of any animal. The cat is easily infected with amoebic dysentery, which usually ends fatally in this animal. So far as the evidence goes, however, it seems certain that it never becomes a carrier—that is, that cysts are never found in its stools. A few other animals—the dog, the rat, the rabbit—have been experimentally infected, but there is no good evidence of the occurrence of the parasite in them except under experimental conditions. It is to be concluded that infection is direct from one human being to another. It can only take place by ingestion of fresh faeces containing the cysts. Flies may play a part in the conveyance of cysts, for Wenyon and O'Connor[5] have shown that cysts can pass through the fly without being injured. The excrement of flies, however, soon dries, and only that which is voided upon food and eaten almost immediately could be effective. Water may be contaminated with infective faeces and the cysts may be thus conveyed.

Significance of the Results

The work which has established the existence of *E. histolytica* in many parts of this country, and has shown that in a special part of the population acute amoebic dysentery still exists, has a significance for the sanitarian. It shows that our personal and social hygiene is still far from what it might be. Differences in the different sections of the population tend to emphasize the significance of personal hygiene in this matter. The highest percentage of infections was found in an asylum population. There seems also to be a significantly high frequency of infection among miners, among whom certain helminthic infections are known to be prevalent. The environment in which they work is probably defective from the point of view of sanitation. The high figures for natives of tropical countries may partly depend on the same factor. Wenyon and O'Connor[5] found a very high percentage of infections (13·5 per cent. found on one examination) among 524 healthy natives in Alexandria. Nevertheless, that it is by no means easy to prevent the spread of these infections is seen from the fact that they occurred among 41 university and school cadets examined at Liverpool—youths whose home surroundings would be satisfactory. Some of the homes visited in the course of the investigations of Liverpool children were poor and dirty, but others were clean and comfortable, yet *E. histolytica* infections were found in both.

The tendency of this work, confirmed by and confirming most of the other work on this subject during and after the war, has been to reduce the importance of *E. histolytica* as a cause of disease. Although this parasite is widely prevalent in this country, yet dysentery is very infrequently caused by it. Nor does it appear now that the facts are very different in tropical countries. We owe chiefly to Dobell[4] the conception that *E. histolytica* occurs normally in the healthy carrier, who passes cysts, and is therefore the medium through which the infection is spread. In him the tissue of the intestine destroyed by the parasite is replaced at an equal rate by new tissue and so no dire results ensue. Any departure from this balance between host and parasite is dangerous to both—to the host because he contracts dysentery, to the parasite because in acute dysentery its chance of finding another host is very much reduced. This reduction depends on the fact that in acute dysentery the amoebae, which are powerless to spread the infection, are passed in the stools. Since the sufferer with acute dysentery is not dangerous to others, amoebic dysentery cannot become epidemic in the same sense as do many diseases of bacillary origin. Outbreaks of dysentery, whether at home or abroad, are mainly bacillary. Even in tropical countries only a small percentage of dysentery is amoebic. It must be noted, however, that acute amoebic dysentery may be more common in Great Britain than has been supposed. Ludlaw[7] found three cases of indigenous amoebic dysentery in no long period after he began to search for them. They may in this country be concealed under such names as "hepatitis," or "ulcerative colitis," for it was among such cases that Ludlaw found the examples just cited. Perhaps the chief significance of this work for the British physician is that he should have the possibility of amoebic infection in mind when diagnosing such cases.

Yet, when all is said, there remains an impression, which may be well founded, that the acute case is significantly less common in this country than abroad, in comparison with the number of persons infected with the parasite. The possibility that this impression is correct should be kept in mind, and wherever possible statistical evidence relating to it should be obtained. Speculations as to the cause of this difference are obviously of little value until we are quite sure that the difference exists.

MEDICAL, SURGICAL, OBSTETRICAL

EXTRAGENITAL CHANCRE

THE situation of the chancre seems to make the following case worthy of record

A Chinese woman of the farmer class 23 years of age married for four years but without children came to hospital complaining of considerable swelling and pain in the right eye of twenty days duration

On examination the whole of the conjunctiva of the right eye was found to be oedematous and chemotic The cornea was clear A hard mass occupied the bulbar conjunctiva below and to the inner side of the cornea This mass had a very definitely cartilaginous feel was well circumscribed and was slightly concave forward

It was ulcerated in the centre leaving a raw area with a thin serous discharge which on removal produced a free serous discharge and a few fine points of haemorrhage The whole mass could be dislocated outwards by making the patient look upwards and by drawing down the lower lid The submaxillary gland on the same side was enormously enlarged and very hard but the preauricular gland had escaped and no other glands were palpable

After a preliminary washing with saline smears were made from the sore and were stained by Noguchi method The slides showed *Treponema pallidum* to be present in very large numbers The blood serum of both the patient and her husband were at this time negative to a modified Sachs-Georgi precipitation test The husband and the father of the patient were seen at the same time and no sign of a recent or old syphilitic infection could be found Active syphilis in other members of the family was denied

It is not possible to trace the source of infection in this case Syphilis is very rife in this town (a large garrison town just outside the Great Wall of China), and a very large number of extragenital chancres are seen In the course of two years' work in this place extragenital chancres have been seen in the following situations lips (several) tongue (frenum and body), tonsil, mammae, abdominal wall and rectum

BISMUTH SODIUM POTASSIUM TARTRATE IN THE TREATMENT OF EPILEPSY

IN this Territory there are many cases of epilepsy, and one meets numerous cases of epileptic insanity In some of these cases I have found *post mortem* pachymeningitis with adhesions between the dura and the pia arachnoid Considering that syphilis was the cause of this, I treated similar cases with weekly injections of the compound bismuth salt, in 3-grain doses intramuscularly This treatment was begun in October 1923 A report was sent to the P M O of this Territory in December of that year, to be incorporated in his annual report The acting P M O has now suggested that I publish some notes of the cases treated

Case A—Admitted in October 1923 suffering from epileptic insanity Just after a severe fit this man broke the arm of another native with a stick He was given 3 grains of the bismuth salt weekly for six weeks No fit occurred for nine months and he appeared normal On August 21st 1924 he had three fits He is now receiving 3-grain injections every four days and there has been no further recurrence of the fits

Case F—Admitted in March 1923 suffering from epileptic insanity This man had I understand been sick for some years in his own village but as he had become very noisy and obstreperous the chief of his village brought him to the administrative officer In the mental hospital he could with difficulty be controlled and had from time to time to be forcibly restrained as he threatened to kill attendants and other patients One curious symptom was noted when an attack was about to come on he spoke and sang in a falsetto voice The chief attendant observed that this always preceded a fit or an attack of noisy obstreperousness From October to December 1923 he received ten injections of the bismuth tartrate Since January he has been quiet and amenable gives no trouble and is quite rational

Case K—An epileptic maniac aged 18 had had epileptic fits for at least three years He was admitted because he killed his mother after an acute attack of epilepsy Treatment by [illegible] was started in October 1923 the night when he had been almost daily occurrences ceased after one week and he became quite rational Ten injections were given This man returned to his station after January 1924 He was quite well till August 1924 when he had a fit Injections have again been started

Case N—A female aged about 30 admitted under magistrate's order to the lunatic asylum on August 10th 1924 showing [illegible] symptoms of acute mania She talked or shouted incessantly slept very little refused to wear any garment and would not answer when spoken to On August 12th she was discovered to have white and native staff to such an extent that [illegible] a 3 grain injection of the bismuth salt The result was marvellous she slept on that night and has been quiet and tractable ever since The injections are being repeated every four days till ten have been given

In my opinion in the majority of instances native insanity in the Territory is related to syphilis As a routine treatment now all patients receive injections of the bismuth salt In cases where no improvement results I take it that the disease is not syphilitic in origin

I add short notes of a case seen in the civil hospital

A girl aged 6 was admitted with epilepsy complicated with incontinence of urine each night From October to December 1923 she received weekly injections of 1 grain of the bismuth salt After the first injection the fits which had been of almost daily occurrence ceased and also did the nocturnal incontinence She was discharged in March 1924 apparently cured She was seen again to hospital in June because of a recurrence of the fits She received other ten injections and so far there have been no further fits The incontinence of urine did not recur

Whether the cure or relief of patients treated in this way will be permanent or not it is not yet possible to say but when one considers the improvement in the condition of the patients themselves and the increased comfort of the attendants and other patients, and as long as one sees no bad result from the injections I think it is well worth while to continue this treatment

The bismuth sodium potassium tartrate used is that made at Nairobi by the Kenya Medical Department

ACUTE TORSION OF THE APPENDIX

As I can find no record of this condition in the literature at my disposal I venture to record the case in the hope that it may be of interest

The patient a man aged 43 sent for me on October 5th 1924 as he had severe cramping pains in his right side He had had pains for two or three days previously but had been able to go about his work—selling butcher meat from his cart in the street He had never had any previous illness that he could remember

On examination I found a hard firm swelling over the appendix area and considerable tenderness on deep pressure There was little rigidity of the abdominal muscles The pulse rate was 100 and the temperature 98.2° The tongue was dry and coated and the breath often sour He was removed to Hawick Cottage Hospital for operation

Operation—When I opened the abdomen some clear fluid escaped A deep purple patch of fat presented at the ileo-caecal region This was adherent to the parietes by recent adhesions which were easily separated The mass was then delivered It was found to contain the appendix which was acutely twisted near its base as the pedicle of an ovarian tumour with twisted pedicle—and the fat was the mesentery of the appendix rolled round and round The centre of the mass was quite black The mass was removed in the usual way it measured about 3 in long and 1 in broad The abdomen was then closed Recovery was uneventful and the patient was discharged from the hospital on October 24th

There was an excessive amount of subcutaneous fat and the mesenteric fat was also increased in amount I imagine that this unusual amount of fat in the mesentery of the appendix may have determined a torsion

Hawick A C MALLACE M C M S M B, Ch B

POST-OPERATIVE THIRST

THE boracic acid spray suggested by Dr T D Hart (October 18th p 717) for this distressing condition seems to be quite efficient but the prevention of it is even more desirable This is carried out in abdominal operations by pouring into the peritoneal cavity just prior to closure of the wound, a quantity of warm normal saline A pint of fluid may advantageously be administered by this route There is rapid absorption and no unfavourable effects The treatment is now to be recommended in septic cases

NOTIFICATION OF PUERPERAL SEPSIS

COMBINED DISCUSSION AT THE ROYAL SOCIETY OF MEDICINE

THE Sections of Obstetrics and Gynæcology and of Epidemiology and State Medicine and the Society of Medical Officers of Health united in a discussion at the Royal Society of Medicine, on November 6th, on "The notification of puerperal sepsis." Dr. H. RUSSELL ANDREWS (President of the Obstetrical Section) was in the chair, and there was a very large attendance.

Origin and Scope of the Discussion

The CHAIRMAN said that the idea of such a discussion originated in a letter addressed by Sir George Newman in May last to the Section of Obstetrics and Gynæcology, in which he stated that the Minister of Health was anxious to take such steps as were possible to reduce the incidence of maternal mortality, and particularly of puerperal sepsis, and asked for observations as to the administrative action which might suitably be taken. The Council of the Section referred the matter to a subcommittee, consisting of Sir Lewis Mackern, Mr. Aleck Bourne, Dame Janet Campbell, and himself, which reported as follows:

"Any case in which there is a rigor or a temperature of 102° or higher for twenty-four hours, during the first ten days after confinement or abortion must be notified. Get rid of the official term 'puerperal fever' and use in its place the term 'puerperal sepsis.' Puerperal sepsis is a febrile condition of the nature of *wound infection*, arising after labour or abortion, due to bacterial invasion from, or absorption of, products of bacterial action from some portion of the genital tract."

In reply to this Sir George Newman had pointed out how important the matter was, as it might influence future legislation, and therefore it was thought well to arrange for a combined discussion. Whatever reply was decided upon at that meeting might be taken by the Ministry of Health as the considered opinion of the two Sections and the Society taking part. The present position of the notification of puerperal sepsis was most unsatisfactory. Many patients suffering from this condition were left without adequate treatment, and the cases were not notified until death was imminent. Dr. Fothergill of Manchester had stated that in 1911-14, out of 200 areas, in 93 the total of deaths from puerperal fever was larger than the total of notifications. One of the results of the present discussion ought to be the provision of beds for women suffering from puerperal sepsis. Cases were sent to hospital frequently too late for treatment—chiefly adequate nursing—to be of value. The subject bristled with difficulties, but he called for constructive criticism. The discussion must be limited to administrative action, terminology, and definition of notification. Ample opportunity would be afforded at the Congress of Obstetrics and Gynæcology in London in April next to discuss causation, prevention, and treatment. He read a letter from Sir Francis Champneys, who suggested that a resolution should be sent to the Ministry of Health asking for arrangements to be made whereby the notification of all fatal cases—or, if preferred, all cases of puerperal fever—should be accompanied by the statement as to who actually delivered the woman. Until this was known, Sir Francis Champneys said, they could not get on the track of the cause.

Notification of Suspected Cases

Dr. J. S. FAIRBAIRN said that the general principle underlying the recommendation of the subcommittee was that notification was useless unless the early and suspected cases were included. He found it helpful to bear in mind the type of case that would be considered a danger to be nursed in a ward with other lying-in patients. True, the risk of contagion was very much less when the patient was already isolated in her own home, although then there was a risk of the conveyance of infection to others by doctor, midwife, or maternity nurse. In domiciliary practice, however, and in nursing homes and small maternity homes, there were not the facilities for the thorough investigation of suspected cases which a large hospital afforded, and this disadvantage might be set against the lessened risk of spread. Dr. W. E. Fothergill had remarked upon the curious fascination which notification possessed for some minds. The best way to escape from being fascinated was to look upon notification as a means to an end, the end being in this case the reduction of the septic death rate in childbirth. Administrative action following notification fell into two categories—one dominated by concern for the individual case, from which point of view it was necessary first to determine the nature of the infection and then to arrange for nursing and treatment, and the other by concern for the public health, which took the form of prevention of the spread of infection and the obtaining and collating of information. The cases notified as suspect should be narrowed down to true genital infection calling for special management and precaution to prevent spread. The care of the individual patient must, however, be kept in the forefront, and the public health measures made as little obtrusive as possible. The doubt must arise whether notification of all suspicious cases was a possibility, and, if it were, whether it would make much impression on the incidence of the disease. In confinements the temperature was often not taken or recorded properly, and many slight fevers escaped notice and developed into serious infections. Some conditions might cause relatively little disturbance to the patient herself and yet be extremely infectious. In all infections it was the carriers and the unrecognized cases which were the greatest danger. The wider casting of the net would certainly add to the burden of the practitioner who did much midwifery, moreover, patients and their households were not altruistic enough always to consider the point of view of the public health or the value of statistical information. One form of notification which did seem reasonable was an addition to the birth notification of the name and qualification of the person actually present at and responsible for the delivery of the woman. The speaker considered that the immediate notification of all suspected cases was out of the question, it would probably involve some amendment of the Notification Act, and certainly some years must elapse before effective measures following on such notification could be set up throughout the country. But was it not possible to organize in some areas obstetric consultations, bacteriological investigations, domiciliary nursing, and a certain amount of hospital accommodation, both for observation and treatment, in which areas practitioners might be asked to notify voluntarily cases of fever in childbed? Much valuable experience would be gained both to the administrative and practising sides of the profession.

Dr. R. DUDFIELD (M.O.H. Paddington) also spoke on the notification of suspected cases. He reminded the meeting that this question was considered by the British Medical Association in, he thought, 1906, and a report was published that any temperature of over 100° lasting for more than twenty-four hours should be regarded as indicating a septic case, and it was implied that this was a case for notification. He would like to see the profession in a position to certify suspected cases. At present the profession was handicapped by being obliged to say yes or nay. He thought also that the Ministry of Health should set up a committee of experts and that questionaries should be circulated to medical officers of health, and through them to the certifying practitioners, the returns being sent to the Ministry for reference to the expert committee. For this work the certifying practitioner ought to receive a fee. If such a procedure was followed it would render needless a great deal of the work of inquiry at present carried out by members of the staff of public health authorities. He suggested that the first part of the subcommittee's report be altered to read:

"Any case in which there is a rigor or a temperature exceeding 100° for twenty-four hours at any time during the first ten days following confinement or abortion must be notified in the instance as a suspected case of puerperal fever."

Although there was a widespread desire to get rid of the official term "puerperal fever" struck out, for legal purposes he thought the term should be retained, it was the term which was in use in other countries.

Better Supervision of Midwifery Practice

Dr R A Lyster (M O H Hampshire) said that investigation into the possible causes of maternal mortality always led to one result—namely, that the chief and almost sole cause was bad midwifery practice The level of midwifery practice could be substantially raised by efficient supervision and inspection The Midwives Act was intended to create a body of midwives practising under close supervision and inspection, but that intention had never been carried out By influence through their societies midwives had successfully prevented the organization of schemes whereby their work could be properly checked and supervised with the result that twenty years' working of the Midwives Act had resulted in little or no improvement in mortality connected with midwifery or mortality among newly born infants The speaker referred in this connexion to the working of the Notification of Births Act, 1907 midwives although they had to notify the birth within thirty six hours had succeeded with the support of the Central Midwives Board in preventing any official visits to the house by health visitors during the first ten days, and it was a striking fact that it was during those ten days that the mortality among mothers and infants had shown so small a diminution during the last twenty years In an area in which for a time the health visitor called during the ten days it was notorious that nearly all breaches of the Central Midwives Board rules by midwives were discovered by the health visitor, it was also flagrant that a very large proportion of the ophthalmia cases discovered were noticed for the first time on the day when the health visitor first called His experience was that a sufficient service of competent midwives—for which the Ministry of Health suggested that large public payments, either direct to midwives or to nursing associations, should be made—could be secured at once in most districts by increasing the supervision of their work In practice the payment of subsidies to midwives in sparsely populated districts was unreasonably costly and it was far cheaper and more satisfactory to provide maternity homes With regard to notification the speaker referred to the pathetic faith exhibited by some people in this procedure Notification unless accompanied by substantial schemes of practical utility, was worthless from the preventive point of view A document issued by the Ministry of Health stated that there should be investigation by the medical officers of health of all maternal deaths due to childbirth and of all cases of puerperal infection whether fatal or not Apparently it was to be left to the medical officers of health to get into all kinds of trouble and difficulty in making inquiries concerning the work of private practitioners He hoped that no medical officer of health would undertake such investigations unless and until the medical profession assented to the proposal This proposal of the Ministry should be considered at once by the British Medical Association and that body should advise its members as to their attitude

1 General Inquiry into Puerperal Morbidity

Dr T Watts Eden said that evidently the notification of puerperal fever was not satisfactory Dame Janet Campbell had said, with official moderation, that it was unsatisfactory and incomplete and Dr W E Fothergill had stated that not 4 per cent of the cases of puerperal fever were notified To the speaker this was the salient fact of the situation The present system of notification had completely broken down Those who saw cases of puerperal fever in consultation were always asked two questions was it a case of puerperal fever, and if so must it be notified? There was a good deal of honest doubt especially in the early stages as to whether a case was puerperal fever or not and even if it was the practitioner liked to call it by some other name if he could The idea was fixed in the public mind that if puerperal fever occurred the doctor was to blame The doctor would notify tuberculosis or eruptive fevers but not puerperal fever if he could help it Until the support of practitioners was forthcoming there could be no progress He thought it a mistake to approach the subject at all from the narrow portal of notification What was required was to bring under review the whole field of puerperal morbidity This would evade the difficulty caused by reluctance of the practitioner to notify How often was a mild febrile disturbance in the puerperium converted into a severe case of sepsis by injudicious management or some operative procedure? The whole field of puerperal morbidity could be explored if provision were made for the reception of midwifery cases at hospitals The present provision was scandalously inadequate If a system of puerperal visitation wards were organized to which practitioners were encouraged to send all the case that went wrong—the lacerations that did not heal the cases that became febrile—the notification of cases properly diagnosable as puerperal septicaemia would be made by the institution not by the doctor from whom the odium of notification would be removed Such a scheme could not be undertaken under the voluntary hospital system but only with State assistance Dr Herbert Williamson had suggested that it was a subject for a Royal Commission That might be the enthusiasm of the obstetrician but it was certainly worthy of inquiry by a strong committee, partly medical, partly lay The evolution of some form of national midwifery service was overdue Such a study as he had suggested would enable the Ministry of Health to get in touch with clinical realities and the practical needs of the situation

The Difficulties of the General Practitioner

Dr C E S Flemming (Bradford-on Avon) said the notification was only a part and by no means the most important part of the process of prevention He agreed with the proposal to replace the term "puerperal fever" by "puerperal sepsis" he still term made notification a burden to the conscientious practitioner it forced him to notify every case with a temperature or to look for a definite specific disease and that without any spots or stigmata to guide him There were, no doubt, conditions not due to sepsis in which there was equally a rise of temperature within ten days and lasting for more than twenty-four hours, one of the most frequent being influenza The diagnosis and selection of cases for notification must be left to the medical man in attendance who would be only too grateful if the suggestion made by previous speakers materialized that a second opinion should be made available The speaker believed that notification at the present time in county areas was made to the wrong person, for it often happened that the practitioner was required to his natural disinclination, to notify a case to a medical officer who was his rival in practice He knew of a medical man who had a case of severe puerperal sepsis, and eventually discovered that the district midwife looking after the case was at the same time nursing two other cases in the same condition (both of them patients of the district medical officer) neither of which had been notified nor had the nurse been informed that they were septic Another reason why notification should be made direct to the medical officer for the county was that he was the officer controlling the midwifery service It should be made not only a moral obligation but a statutory duty to inform the midwife or maternity nurse in attendance of the fact that a case was septic He thought also that when a medical man giving ante natal treatment discovered that the surroundings of the patient were not suitable he should have the duty of notifying the local authority What was the good of notifying a septic case unless it could be removed out of harm's way and to some place where it would receive efficient treatment At present in most districts, the isolation hospital was the only suitable place

1 Comprehensive Definition

Dr W Butler (Medical Officer L C C) said [illegible] came about after so many years of statutory notification, that a disease remained so elusive The truth was that on the one hand, there existed a series of pathological phenomena associated with the puerperal state of a variable character, both in origin and symptomatology as to [illegible] obligatory inclusion under any term or group of terms,

and, on the other hand, there was the tragic history of puerperal sepsis, the sombre background of the past projecting itself and presenting what, in the light of modern medicine, seemed an anachronism—a preventable catastrophe that would suggest a culpable responsibility The general practitioner was not less solicitous than the medical officer that the dangers of childbirth should be reduced, but he approached the problem from a different angle, and he had *personal interests which he naturally thought* had a claim to consideration The difficulties of the practitioner were real, and should be sympathetically apprehended Dr Butler thought that the *suggestion* of the subcommittee as to what cases should be notified had *the merit* of precision, and, quite fortunately, it embraced a variety of conditions which it would be incorrect and misleading to describe as puerperal sepsis—such, for instance, as a common cold, not infrequently contracted during labour, an attack of influenza, or the kindling of a latent tuberculosis Why not call it a sustained puerperal pyrexia, and thereby get rid once and for all of a bugbear? Sustained puerperal pyrexia was a suitable condition for notification, although how far it was compatible with the provisions of the Infectious Diseases Notification Act to make known only a clinical condition common to a number of diverse diseases was another matter which need not be discussed at the moment This would certainly be an innovation, but it would lead to administrative action involving the closest co-operation of medical officer and practitioner, and would be likely to be very fruitful in results It was, in fact, the only kind of action appropriate to the circumstances, and if a departure from the stereotyped procedure had to be made and special measures devised accordingly, the occasion justified such an innovation

Administrative Measures

Dr H Scurfield (late M O H Sheffield) said that all the speakers appeared to be agreed that the notification of puerperal sepsis had failed One reason was an idea prevailing in many districts that sepsis occurring after miscarriage did not require to be notified His own feeling was that it would be better to put forward a proper administrative scheme before bothering about the question of the exact condition to be notified One speaker had said that the notification of tuberculosis was actually carried out, he did not think that medical officers would agree as to that, but the zeal in carrying out the notification of tuberculosis varied in different areas with the efficiency of the administrative measures that could follow upon notification Another disease now notifiable, ophthalmia neonatorum, was like *puerperal fever in the respect that it* seemed to imply a slur upon the practitioner, but the notification of this disease was fairly well carried out, again because administrative measures had certainly become more efficient This idea of a slur upon the practitioner would not interfere with the proper notification of puerperal fever when such administrative measures were available In Sheffield the only institutional provision was the Poor Law hospitals, and that raised a big question Such cases were not admitted into the infectious diseases hospitals under the control of the corporation, if they were so admitted in any area it would be necessary to engage a special staff of nurses, and to have gynaecological specialists at call He urged that this question of a slight alteration in the definition of puerperal fever should be coupled with a strong recommendation that an administrative scheme be organized for every district, urban or rural

Popular Prejudice against Notification

Sir Ewen Maclean said that those familiar with the subject were aware that Wales was an 'awful example' in the matter of maternal mortality, and in particular of mortality from puerperal sepsis When the figures for the country generally were 4 11 deaths per 1,000 births, the figure for Wales was 5 41, and the single factor which was most prominent in these late figures was puerperal sepsis The Consultative Council of the Welsh Board of Health was so much impressed with the high puerperal mortality in Wales that it sought and obtained the consent of the Ministry of Health to visits by its members in several parts of Wales to investigate conditions on the spot In Wales, as in other parts of the country, non-notification was largely practised The cause for this which emerged in the course of the inquiry was one which went rather deeper than the suggestions made in the present discussion Directly or by implication the blame had been laid upon the doctor or the midwife, but the real reason why notification was not much more successful was found to be, in Wales, the extraordinary complacency of the people themselves They did not mind whether the condition was notified, and in many cases they did not want it to be notified It was the patient who raised objection, or at least was indifferent But if it became a matter of experience that notification resulted in advantage to the individual patient, then notification would become a popular thing, and thus would sweep away all the disabilities now attached to notification by practitioner or midwife

Hospital Accommodation for Puerperal Cases

Professor Louise McIlroy considered that notification under present conditions would always be a failure It would always bring practitioners into disgrace Enormous courage was required on the part of the practitioner to suggest it to his patient If he was conscientious he had many black marks against him at the Ministry of Health, while the unconscientious practitioner had a clean record there Again, to rely on temperature as a mark of puerperal sepsis was out of date Was it to be said that a case of puerperal sepsis with streptococci in the blood was in the same category as another case in which there was a slight laceration of the cervix and a temperature and which cleared up after a day or two? Another reason for the failure of notification was the lack of adequate treatment for the notified patient She agreed that some influential committee should sit on the question of the whole organization of obstetric practice, and one of the great reforms which the Ministry of Health might bring about would be the setting up of a large hospital, preferably in London, devoted entirely to the treatment of puerperal sepsis If cases were notified to the medical officer of health of a district he had no power to carry out any adequate treatment, and patients did not like to be sent to a Poor Law infirmary This discussion on notification was merely a small part of the question Another matter which might be taken into account was the absence of facilities for practitioners to take intensive courses in midwifery

Dr L W Goodall (medical superintendent North Western Fever Hospital) said that cases of this character had been admitted to the infectious fever hospitals of the Metropolitan Asylums Board since 1912, and were placed under the charge of the medical officer who had been in the service the longest and had the most experience of this disease, moreover, the authorities of the hospital were always at liberty to call in specialists, and frequently did so The misfortune was that many of the cases came too late—practically dying—while others which came were travel cases, not puerperal sepsis at all It would be a good thing to concentrate cases of puerperal sepsis in one or two hospitals

Other Points in Discussion

Dr Mary Kidd regretted to hear so much criticism of midwives, who were an excellent, hardworking body of women They were ill paid, and incidentally it would be a good thing if local authorities could make them an allowance for rubber gloves and sterilized outfits With regard to health visitors, many mothers of the poorer class would resent the appearance of a health visitor in the very early days after confinement Many of these health visitors knew nothing about midwifery, and their interference might be hard on the midwives With regard to Poor Law institutional accommodation, this might be acceptable if only the relieving officer could be got out of the way

Dr Stevenson (Registrar-General's Department) said that it would be useful to know in what practice—whether midwives' or midwives'—the cases of puerperal sepsis occurred This could be readily established from existing records He had been struck by the fact that, indeed not after the war, when, presumably, the proportion of the

attended by midwives declined owing to the return of practitioners to civil duties, there was a sudden and considerable rise of mortality from puerperal fever He added that the Registrar General no longer used the term 'puerperal fever" but puerperal sepsis" His own view was that the former was the proper term but strong representations were made a few years ago, and he bowed his head to the storm

Dr J ROBERTSON (M O H Birmingham) agreed with previous speakers that it very frequently happened that cases arrived at hospital so late that it was impossible for the best specialists to prevent a fatal issue The whole question of obstetric administration needed to be reviewed, and he was convinced that not only practitioners, but midwives and local authorities, desired to co-operate in a general scheme for the betterment of midwifery

Dr REMINGTON HOBBS thought that the limitation of notification to cases which had a rigor or a temperature of 102° would leave a vast number of patients in jeopardy It would leave many women in pain and suffering for days when they could be relieved Many cases did not show these manifestations some indeed, ended fatally in which the temperature had been little above normal He would like to add to the definition that there were cases in which the uterus became absolutely obstructed and others in which it became partially obstructed, and that septicaemia could occur in both

The Chairman (Dr PISSELL ANDREWS) said that the discussion had been very useful and it remained now for the subcommittee to draft a reply to the Ministry of Health Whatever answer was sent would deal not with small points, but with broad policy and would most probably include a request for such an inquiry as had been suggested by Dr Eden and other speakers

TUMOURS OF THE BREAST

A MEETING of the Aberdeen Medico-Chirurgical Society was held on October 30th, when the President Dr G M DUNCAN, delivered his presidential address on tumours of the breast

Dr Duncan's experience included several hundred of such cases After some preliminary remarks upon the importance and difficulties of histological examination he dealt first with the carcinomas Points of interest in these tumours were the rarity of their occurrence in the male breast (in his series only six occurred in males) the difficulties of diagnosis in the early stages and the extraordinarily high percentage of carcinoma in the case of breast tumours Dr Duncan described the method of rapid diagnosis by examining sections during an operation, and thought that this method might be more extensively used provided that the pathologist had the necessary experience of preparing and diagnosing such sections Illustrative cases were described where the method had been of considerable value The different varieties of breast cancer were then described, and special reference was made to the difficulty of differentiating cancer commencing in a mastitis breast and of distinguishing the malignant types of papilliferous cyst-adenoma Dr Duncan drew four general conclusions (1) Cancer of the breast in young women tended to be much more malignant than in those of greater age (2) Cancer associated with inflammatory conditions of the breast often tended to be peculiarly malignant (3) As a general rule, the more cellular the growth the more malignant it was (4) It was unwise to draw merely from the size of the growth any definite conclusion as to malignancy locally, and also as regards the occurrence of metastatic deposits Cases were cited to show that while a large growth might be removed with complete success rapid local recurrence or the development of metastatic deposits might follow the removal of a small growth Emphasis was laid on the occasional occurrence of metastatic growths producing definite physical signs where the primary tumour in the breast was so small as to require the most careful examination for its detection Dr Duncan then described other types of breast tumour such as fibro-adenoma and the very rare sarcoma he referred also to inflammatory conditions including syphilis and tuberculosis He suggested that some of the vague fibrous conditions found in the breast might be of syphilitic origin

THE SEMON LECTURE

MALIGNANT DISEASE OF THE OESOPHAGUS

On November 6th, with SIR WILLIAM HALE-WHITE, K C M G, C B, in the chair Dr I GUTZEIT [illegible] delivered the University of London Semon Lecture on malignant disease of the oesophagus The lecturer spoke in French and illustrated his remarks with a number of lantern slides

Dr GUTZEIT stated that cancer was the most frequent affection of the oesophagus and occurred in about [illegible] patients suffering from disease of the oesophagus It was six times more frequent in males than in females and [illegible] for the most part between the ages of 55 and 65 the youngest patient referred to by Dr Gutzeit was a boy 14 years of age The most frequent site was the lower third and after that the middle third the upper third Inflammation of the mucous membrane due to chronic irritation especially of alcoholic origin, was held to be an etiological factor but the lecturer also drew attention to the effects of psychical factors which predisposed to cancer of the oesophagus, and he quoted instances of patients who had developed carcinoma of this part after [illegible] from spasm of psychical origin In the course of inflammation of the mucous membrane patches of leucoplakia developed and it was in these patches that cancer [illegible] appeared later

Symptomatology

Coming to the symptoms of carcinoma of the oesophagus, Dr Gutzeit stated that dysphagia occurred in 93 per cent of cases This dysphagia was painful and it began in an abruptly the patient suddenly finding difficulty in swallowing a morsel of bread or meat This feature was responsible for the so-called latent period of disease pain only occurring when the growth had [illegible] structures Another frequent symptom was excessive salivation a implying reproduction canal of the [illegible] length of time during which food had to be rejected Dr Gutzeit emphasized that the tumour [illegible] and completely the wall of the oesophagus [illegible] was uncommon in the early stages and dilatation with so-called regurgitant vomiting was only [illegible] The extreme emaciation in this disease [illegible] to starvation it was not a malignant cachexia Other minor signs included the expectoration of [illegible] phlegm a peculiar fetor of the breath and a [illegible] coating of the base of the tongue and [illegible] lingual leucoplakia

While spread of malignant disease to the [illegible] by tastes in the veins and lymphatics was rare [illegible] continuity frequently occurred Extension to the mediastinum of the tumour or [illegible] gave rise not only to pressure on the air passages but also to inflammation and destruction of the trunk The left recurrent laryngeal was often involved this was found to be the case in 20 [illegible] and especially the left [illegible] perforation occurred as a late [illegible] Pleurisy complication such as bronchopneumonia or abscess of the lung frequently resulted from [illegible] and extension of the growth to the [illegible] occurred Pulmonary tuberculosis was a [illegible] complication Severe haemorrhage resulting from [illegible] or a large vessel was not infrequent [illegible] this disease

Clinical Varieties

Dr GUTZEIT next dealt with the [illegible] part disease of the oesophagus A [illegible] where the growth was [illegible] was very rare Ulceration [illegible] slow but in young subjects [illegible] carcinoma of the [illegible] was usually pulmonary [illegible] while in [illegible] was the [illegible] part to [illegible] [illegible] In the case of malignant disease [illegible] [illegible] occurred [illegible]

Carcinoma secondary to growths in the trachea and in the breast had also been reported. Multiple growths sometimes occurred, and in cases treated by radium the growth sometimes appeared in other parts of the oesophagus while the primary carcinoma remained fibrosed. Apart from oesophagoscopy, the physical signs of malignant disease of the oesophagus were few. The passage of a tube or bougie revealed only the presence of stenosis, and a radiographic examination after an opaque meal showed little more. Direct examination through an oesophagoscope, however, would show the growth in its earliest stages. Dr Guisez then described his method of using this instrument.

The common varieties of oesophageal growths were polypoid, ulcerous, and scirrhous in type. The first consisted of more or less pedunculated exuberant masses of epithelium which occupied the lumen of the canal and bled freely on being touched. The ulcerous form consisted of infiltrated patches of denuded epithelium with raised, hard edges. The scirrhous variety was rare except in the lower third of the oesophagus, it consisted of hard, fixed masses under the epithelium which rapidly infiltrated a segment of the wall and gave rise to stenosis.

These three varieties were sometimes combined. The constant features were the immobility of the growth and the bleeding on touching, while a microscopical examination of portions removed through the oesophagoscope would clinch the diagnosis. Malignant disease of the oesophagus had to be diagnosed from simple stenosis, from spasm, and from pressure on the oesophagus from the outside, and the oesophagoscope would enable any of these conditions to be eliminated.

Prognosis and Treatment

The prognosis of the disease was naturally grave, but factors such as the slowness of the growth, the absence of pain, and the relative absence of generalization rendered disease in this part not so distressing, at any rate in the early stages, as malignant disease of other portions of the alimentary canal.

The ideal treatment of carcinoma of the oesophagus was complete removal or destruction of the growth. Surgical removal was up to the present generally out of the question. Attempts had been made to resect growths of the upper end of the oesophagus, but the mortality rate was very high. Intrathoracic growths had also been operated upon, but only one successful case was so far reported in 1919 a patient operated upon by Thoreck was still living, eight years after removal of the growth.

Application of radium seemed a more hopeful method of treatment, particularly as the growths generally consisted of squamous epithelium of the basal-celled type, which was most susceptible to the action of radium. Dr Guisez stated that he had employed radium in the treatment of 270 cases during the last fifteen years, always after a microscopical confirmation of the nature of the growth. In some cases the use of radium proved purely palliative, but in 39 cases life had been prolonged for more than eighteen months, and in several the growth had not reappeared—in one case for as long as eleven years. The disappearance of these tumours was watched through the oesophagoscope and generally no trace was left.

The lecturer then described his methods of using radium. It was essential that the exact site of the growth be known, that the patient be not too exhausted, that neighbouring structures be not involved, and that the patency of the tube be still sufficient to allow radium to be applied. The distance of the growth from the mouth was first accurately measured and radium introduced on a special carrier so that it was exactly opposite the neoplasm in the oesophagus, the upper extremity of the carrier being firmly fixed by tapes round the head. These carriers were special long sounds, which were very liable to slip up above the growth. The radium bromide usually employed was about 10 to 12 centigrams of platinum platinum screens (1·5 mm.). Five or six applications of up to ten hours every other day were generally given. If the growths were observed through the oesophagoscope the action which happened was the disappearance of the tendency to bleed on touching with a sound, and in favourable cases the growth gradually disappeared. (Some striking illustrations, drawn from actual oesophagoscopic views, were shown to demonstrate this.) In summarizing the results of this treatment, Dr Guisez remarked that in recent years they had been much more favourable, particularly when it was remembered that he had an increasing number of advanced cases sent to him.

The lecturer finally dealt with other palliative methods of treatment, referring to the operation of gastrostomy, which was often, he said, delayed too long. He also described the use of soft rubber tubes of the Pezzer catheter type, which were more easily tolerated than the solid tubes usually recommended, and he regarded such intubation as preferable to gastrostomy.

PROGRESS IN PREVENTIVE MEDICINE

Dr McVail's Address

The presidential address was delivered by Dr J. C. McVail before the Section of Epidemiology and State Medicine of the Royal Society of Medicine on October 23rd. Taking the progress of preventive medicine as his subject, the President reviewed the advances that have been made since the commencement of the modern sanitary era, when William Farr began his great work at the General Register Office, and then proceeded to indicate the directions in which further progress may be made.

Early in his official experience Dr McVail became impressed with a fact which had since become obvious to the most cursory observer. In modern schemes of public assistance there was risk of diminution of the sense of personal and family responsibility, and a tendency to rely on imperial taxes or local rates for services which should be provided by individuals for themselves and by parents for their children. No progress could be regarded as satisfactory which tended to undermine a man's independence and strength of character. In order to guard against such results, whatever measures were adopted in the future should be subject to three principles: (1) Insurance in the provision of services which the individual cannot be safely left to secure for himself. Definite personal contribution to a fund created beforehand for meeting the cost of contingent outlay on behalf of individuals was incomparably better than resort to current rates and taxes. (2) The establishment in practice of the principle of conditional relief as distinguished from unconditional relief, and exercise of due discipline over beneficiaries. (3) Effective education in personal and family health, especially of parents in the rearing of their children, education in self-reliance and foresight, and in the responsibilities of citizenship. Subject to these principles, Dr McVail emphasized two of the directions in which further progress should be made—the routine medical examination of individuals apart from illness and the concentration of matters relating to health alike of the community at large and of the pauper class—under a single authority.

In 1907, at the request of the Royal Commission on Poor Law, Dr McVail investigated Poor Law medical relief in England and Wales, and in a memorandum to his report advised that systematic medical inspection should be established in respect of all ages of life. The family doctor, he said, should at reasonable intervals offer to make examination of those for whose health generally he is responsible. He would acquaint himself with the family history, and note pathological tendencies requiring to be checked. With regard to the children, he would note their physical condition as a whole, their state of development in relation to age, indications of rickets, tubercle, or glandular disease, defects of sight or hearing, and enlargement of tonsils and the like. In connexion with the occurrence of actual illness, he would ascertain whether there was any threatening of dangerous sequelæ, such as endocarditis after acute infectious disease. He would note whether the child's nervous system was being properly developed, and its functional activity sufficiently restrained. As regards the school child, he would see whether school work was being overdone, whether the child was being taught to practise steady application in any specified task, whether it was

being permitted to read books of too exciting or too advanced a character, whether it was being sent sufficiently early to bed and made to rise early enough in the morning, whether it was being punished unwisely for faults due to its physical and mental condition As the child continued to grow into youth, note would be taken whether athletic exercise was excessive and injury to the heart or other vital organ threatened whether, on the other hand, the youth was leading too sedentary a life When the time came the doctor would advise as to the most suitable occupation, having regard to the general condition of health Among women he would see that due care was taken to prevent mischievous sequelae of childbirth, such as uterine displacements or inflammations Among men he would observe any tendency to trade disease, whether their employment was such as made special calls on any vital organs, and if so whether these were reacting properly to the stimulus or threatened to break down Independently of age sex and occupation, the inmates of a household would be offered a general examination of their vital organs, and advice would be given where it appeared to be necessary In old persons attention would be paid to the condition of the arteries in relation to apoplexy, and to parts likely to be attacked by cancerous disease

Though periodical medical examination did not commend itself to the Poyal Commission, there had since that time been a remarkable development on the lines indicated Infant welfare, child welfare, school medical inspection and treatment carried out the principle as regards the young though the work was not done by the family medical attendant but by school doctors and nurses Even as regards adult life much progress was now being made In America several of the large life insurance companies provided and paid for medical inspection of the insured They did so, not on grounds of benevolence but of economy and finance, and it was claimed that a large saving in life and capacity for work was made under this scheme The work was done by medical men employed, not directly by the insurance companies, but by a life extension institute

Evidence was accumulating rapidly to show that this common sense method, generally applied and followed by necessary remedial treatment or regulation of personal hygiene would do more to prolong health and vigour than any other measure During the administration of President Roosevelt the system was introduced into the United States Army in respect of commissioned officers and it was reported to be of great value in conserving health A circular by the War Department in 1921 urged the necessity of examinations being carried out with thoroughness attention to detail, so as to enable the Department to apply practically on a large scale the principles of health preservation Between 1914 and 1921 the Metropolitan Life Insurance Company authorized nearly 95,000 physical examinations, and reported that it had been established to the satisfaction of the company that periodic medical examination was justified by the benefit in added life expectancy to the policy holders The question was raised in the address, how far the average general practitioner was at present qualified by his training to detect the very beginnings of disease, but on that point attention was drawn to the fact that under the General Medical Council's regulation such training is now an essential feature of the whole medical curriculum Periodic examination should never be made without the free consent of the individual—the adult for himself the parent for the children

The second matter discussed by Dr McVail had reference to the Poor Law He supported the view that there ought not to be two separate sets of local authorities dealing with health—one for the community at large the other for the pauper class The health functions of the boards of guardians should be transferred to the local authorities under the Public Health Act The Majority Report was however against the policy of break up of the Poor Law including the transference of health functions Recent reconsiderations by a specially appointed body had resulted in a reversal of the majority conclusion on the subject but the important point was that it should be the duty of the health authority to take charge of the health of the pauper class not only in the interest of the latter but of the population at large Excluding lunatics and vagrant paupers numbered perhaps only about 25 per 1,000 of the population, but pauperism, though destitution was a legal criterion, connoted far more than mere poverty and whether it resulted from tuberculosis or alcoholism instability of character, or other cause the public interest required that paupers be under more skilled control in respect of health and character Doubtless many board of guardians went beyond the limits prescribed for them, and on the other hand the area and population under many a public health authority were far too small for efficient administration But the situation should be frankly faced and a great reform in the whole scheme of local government be undertaken

Finally, Dr McVail dealt with the familiar argument that their sanitary efforts would simply result in the widespread survival of the unfit, and lead ultimately to the production of a degenerate race He pointed out that assuming that one-tenth of the births fell below the line of viability during the first ten years of life under present sanitary conditions, and that these could be saved by improvement in the environment, it must not be forgotten that the remaining nine-tenths also shared in the benefits of the improved condition It it was considered a loss to have preserved the weaklings, there was, on the other side of the account, nine times the gain in the form of increased vigour of the fit, and the same condition which strengthened the weakest made also for the survival of the fittest

X-RAY TREATMENT OF UTERINE FIBROIDS

A clinical meeting of the Newport Medical Society was held at the Royal Gwent Hospital on November 5 th

Dr T I Cundy read a short communication on the treatment by x rays of menorrhagia due to uterine fibroid The type of case he considered best suited for this method of treatment was menorrhagia occurring in a patient over 40 years of age, causing weakness and impairment of the general health, and postponing the onset of the menopause It was necessary to exclude the presence of malignancy and suppurative pelvic condition His practice was to administer at one sitting the dose necessary to produce amenorrhoea The improved methods of measurement now available and the increase of knowledge of the biological action of x rays enabled this to be done with a considerable degree of precision He found that the best time for treatment was within the first ten days after the cessation of menstruation The next menstrual period came on as usual but the loss was always very much reduced and thereafter complete amenorrhoea became established In each of the twelve selected cases which he had treated the clinical results had been all that could be desired

Dr Morrell Thomas showed a pathological specimen from a case of haematometra following pregnancy Dr Cuthbert Johnson showed a case of aneurysm of the femoral artery associated with dilatation of the aorta Mr P J Ivens reported upon a case of sarcoma of the upper jaw in which the growth retrogressed in a remarkable manner without treatment but which subsequently recurred The diagnosis had been confirmed by pathological examination The President Mr R J Coulter, showed a small piece of iron copper wire which he had removed from the vitreous of a patient who had been struck on the eye by a shot or cartridge Dr Inchley showed a case of gumma of the lip successfully treated three years ago, and which now showed on x ray examination, extensive deposits in both lungs

---

On October 21 st Dr J A Murray delivered the presidential address to the Section of Pathology Poyal Society of Medicine He dealt with the possibility of remedying the increasing bulkiness of the literature of experimental pathology by developing a pictographic convention which would obviate or at any rate reduce the necessity for long verbal descriptions The difficulties in the way of such a change were exemplified in a series of clear cut experiments in cancer research lantern slides and the peak recommended to the member of the Section the making of further experiments on uniform lines of presentation of their results

Reviews.

INTERNAL SECRETIONS

A work on the *Biology of the Internal Secretions*[1] by Professor F X Dercum of Philadelphia, who described adiposis dolorosa as far back as 1888, would in any case attract attention, and the interesting and suggestive manner in which it deals with the endocrine factor in development, in subnormalities, in neoplasms, in nervous and mental diseases, and in heredity, more than justifies this anticipation This comparatively small book contains much original thought and its hypotheses break new ground, but, though cautiously made, some of these new conceptions can hardly be regarded as proved until confirmed by the necessary research they may well stimulate Tracing the internal secretions from the cellular products of the protozoa into the higher animals, stress is laid on the interrelations of the endocrine glands, and it is definitely stated that *there is no uniglandular disorder*, for more than one endocrine gland is always involved, possibly all of them, and accordingly the relations of the various glands are fully discussed

Perhaps the most striking points in this mature expression of the views of an experienced physician are the importance he ascribes to the thymus gland and his suggestion that the cause of malignant disease may be disorder of the endocrine glands To the pineal gland also Professor Dercum attributes considerable importance as a controlling influence during the period of growth of the body, it undergoes involution at the time of puberty when its work has been completed, and accordingly the symptoms of pineal disease, mainly due to hypopinealism, are explained is due to premature removal of its restraining action Professor Dercum lays much stress on the endocrine function of the epithelial thymus (Hassall's corpuscles) He considers that this provides a substance favourable to lymphocytic life, and that in the status lymphaticus, which is regarded as an expression of inherent feebleness of tissue development, it secretes a vagotonic toxin responsible for sudden death Further, he suggests that enlargement of the thymus, as part of the feeble state of development, leads to overactivity of the antagonistic thyroid and so to exophthalmic goitre, and that as a result of this the chromaffin system also takes on excessive activity, and occasionally the anterior lobe of the pituitary enlarges, also in order to overcome the depressing effect of the enlarged thymus, as is shown by acromegalic features Indeed, acromegaly is ascribed to an enlarged thymus stimulating the anterior lobe of the pituitary to overactivity As the parathyroids contain thymus elements they are placed in synergic relation to the thymus and in antagonism to the thyroid Hypoplasia of one endocrine gland leads to hyperplasia of the antagonistic glands, and disease may result Enlargement of the thymus and lymphatic system is thought to play the principal part in disturbing the balance between the endocrine glands and so favouring the development of neoplasms, for the healing of abrasions, fissures, and ulcers, if no longer controlled by the sympathetic group of endocrine glands (the adrenal medulla, the posterior pituitary, and thyroid), may take the form of riotous hyperplasia This hypothesis helps to explain the usually accepted influence of chronic irritation in the production of new growths But the statement, apparently made in support of this view, that primary malignant disease of the thyroid and of the chromaffin system is practically unknown, cannot be accepted

The discussion of the relation of the endocrine glands to nervous and mental diseases is especially interesting as coming from such a distinguished neurologist, neurasthenia is regarded as the result of functional failure of the chromaffin system, the thyroid, and the pituitary in a neuropath—that is an individual with a morphological and biological defect in the endocrine glands In the chapter on neuropathy and the problem of heredity the transmission of acquired characters is firmly asserted and Weismann's theory controverted on the grounds of clinical experience

ANAPHYLAXIS

The title of Dr Cranston Low's monograph, *Anaphylaxis and Sensitisation*, scarcely reveals the wealth of material dealt with by the author, who, besides giving a full analysis of anaphylaxis, has made a notable contribution to the pathology of diseases of the skin[2] No problem directly or indirectly related to anaphylaxis has been overlooked in this survey, which is brought down to as late a date as the present year Some idea of the scope of the work may be obtained from an enumeration of the subjects examined Anaphylaxis in man, urticaria, drug eruptions, the erythemata, sensitization in tuberculosis, syphilis, and fungus infections, dermatitis venenata, dermatitis exfoliativa, focal infections, sensitiveness of the skin to light, tests for cutaneous hypersensitiveness, and finally desensitization Dr Low makes it quite clear that there is no one explanation acceptable by all the workers on anaphylaxis regarding its own physico-chemistry or the relations of the sensitizing substance (anaphylactogen) to the antibodies or ferments to which presumably it gives rise

The relations of anaphylaxis to immunity must be very close, and Dr Cranston Low, following Vaughan and Wheeler, summarizes them thus the injected foreign protein causes the tissues to produce a specific ferment (antibody) which splits the protein into a non-toxic and a toxic portion Any "specificity" in the reaction is due to the non-toxic moiety The toxic portion, common to all proteins, causes the morbid stimulation of nonstriated muscle, which is the essence of anaphylactic shock, hence the uniformity of symptoms in the same species of animal whatever the protein used When the ferment splits up the protein (bacterium, etc) before it has time to multiply, the animal is said to be immune When the cleavage is less prompt, but sufficiently so to break up the protein before it elaborates the fatal amount of poison, the animal sickens but recovers When the action of the ferment is still less prompt, the protein elaborates enough poison to kill the host In an animal which has recovered, the proteolytic ferment is stored in the cells of the body as a zymogen, which is activated by the second injection of the same protein—this is anaphylaxis This is by no means the only sort of explanation of anaphylaxis that can be given Friedberger's, for instance, is based on Ehrlich's side-chain theory, as follows the injection of the foreign protein calls forth the production of receptors which neutralize the antigen Similar receptors continue to be formed, but remain "sessile" in the cells, when the protein is injected a second time the antigen combines with the antibody and complement to form "anaphylatoxin," which, being a poison, produces the symptoms of shock This theory explains the absence of complement from the blood in anaphylactic shock

One of the most interesting chapters is that on hydroa aestivale, which is a discussion of the biochemistry of photo-dynamic sensitizers It appears that the worst cases of buckwheat poisoning in cattle occur when white or spotted animals eat the plant when in bloom One of the symptoms is an itching erythema Black animals are not affected, nor even are white ones if kept indoors or under cloudy skies White animals put out into the sunshine rapidly develop the dermatitis Ultra-violet light is therefore one of the causal agents But buckwheat contains phytoporphyrin, an ally of chlorophyll and of haematoporphyrin The inference is that the pigment is a photic sensitizer Now in hydroa aestivale haematoporphyrin is very often found in the urine, and is presumably in the blood The inference here is that that pigment is the photic sensitizer of the skin in which there is induced a destructive process Chlorophyll or haematoporphyrin added to a suspension of red blood cells in a strong light causes them to be haemolysed, while in a control tube in the dark no haemolysis occurs

To such an extent are clinical conditions being brought under the category of anaphylaxis that Dr Low writes "Taking everything into consideration, the course which acute fevers run can be explained fairly satisfactorily on the assumption that they are due to bacterial anaphylaxis"

PRACTICAL BIOCHEMISTRY

We heartily welcome *Elementary Practical Biochemistry*,[1] by Professor W A Osborne and Dr W J Young, lecturer on biochemistry in the University of Melbourne, as one of the best handbooks to the laboratory for the junior student that has been published in English But it is more than a laboratory guide, for it gives, under the heading 'Theoretical" (didactic would be a better term), a summary of the points of physiological interest in the subject about to be dealt with practically

The treatment throughout is condensed without any sacrifice of clearness A number of topics are introduced which are of the utmost importance for the beginner, but which are hardly ever dealt with sufficiently fully for him in his textbooks, some of these are "basal metabolism" colloids, and hydrogen ion concentration A feature of the book is that certain subjects of special importance for veterinary students are discussed The treatment of vitamins, chemistry of milk, preservatives of food, and drugs in the urine is admirable, and just what the junior man should know The book is no mere repetition of a course which might have been excellent twenty years ago—it is up to date, it authors are alive to pre ent-day requirements

The only quantitative estimations described are those for the chlorides and phosphates of urine for urea and for glucose even in an elementary treatise the estimations of *uric acid, creatinin, and hydrochloric acid in gastric juice* should have been included Newer quantitative microchemical methods such as those of Folin and others are not described, and there are no figures of apparatus Probably the authors hold that these micro methods do not belong to an elementary work, hence no method is given for estimating the sugar in the blood Possibly for the same reason there is no reference to the colorimeter, to the polarimeter, or to filtration through a Berkefeld filter We have found nothing about the chemistry of the faeces or the chemical aspect of respiration Considerably more might with advantage have been said in the didactic part of the chapter on the physiology of alcohol, and a fuller description given of the chemistry of the washing of the skin—a subject about which the medical student's views are very hazy No method for the quantitative estimation of protein in urine is given, nor, indeed, of protein anywhere, this omission may be excused on the ground that these subjects belong to pathological chemistry, though in reality only the former does No directions are given for the preparation of substances in a pure state We hold with Liebig that nothing in physiological chemistry trains the beginner like having to prepare some of these The acetone method for urea is so extremely simple that it should have been included in any case Every laboratory manual for the junior student should contain a simple method for demonstrating the reducing powers of the tissues whether or not "reductase" is believed in on theoretical grounds There are one or two minor inelegancies, such as 'Points in Pavy," and 'a new lot of Pavy" Probably "Fehling solution" for "Fehling's solution" is an oversight, but "crystallized" has still two l's, on page 114 it is given only one The blank leaf between every two printed pages is an excellent feature of the book, and there is an index

THE PROLONGATION OF LIFE

Under the title of *Health Building and Life Extension*[2] Dr E L Fisk gives a very interesting account of American activities in the prolongation of life and the increase of working capacity The book is a survey of industrial health conditions made by the Life Extension Institute of New York on behalf of a Committee on the Elimination of Waste in Industry, the committee having been appointed by a federation of engineering societies Dr Fisk holds that all forms of disease and physical deficiency can be combated on lines correctly laid down The problem of fatigue has to be solved at its source and the committee's study and research had to be extended so as to include not only industrial problems, but health factors affecting mankind in general

The book is in three parts, entitled respectively "The physical state of civilized man", "The problem of industrial health and working capacity" and 'Preventive, remedial, and constructive measures" In the first part there is discussion of the question of physical degeneration, the extent of disabling illness, the possibility of further extension of the life cycle, the health cycle, and the work cycle, and the value of periodic examination and health supervision In a Government report on national vitality in 1909 it was stated that about three million persons were seriously ill at all times in the United States, and that 42 per cent of this was preventable, with a resulting life extension of more than fifteen years Since that time certain statistics have indicated that an estimated annual loss of thirteen days per head from illness has been reduced by at least a third and the expectation of life has been extended by about nine year In Part II of the volume the effect of many agencies injurious to health is considered including infections, harmful drugs and beverages, *alcohol, and tobacco* food deficiency and excess, foul air, hormone deficiency and excess, physical and psychic strain and apathy and injuries to sight This section of the volume concludes with a brief chapter on the economic loss from preventable disease and *sub-standard health conditions* Part III is devoted mainly to questions of organization or control measures, by the Federal Government, by individual States of the Union, by communities, and by industries Voluntary agencies are also dealt with, and the concluding chapter relates to special drives against disease

It will be seen from this indication of its contents that Dr Fisk's volume covers a wide field It is vigorously written and graphically illustrated To health authorities and health officers in the country it reveals in convenient compass what is being done in the United States That country admittedly followed the lead of Britain, but in freshness of outlook and initiative it is now in some directions perhaps surpassing its teachers who in their turn ought to be willing to profit from their pupils

PSYCHOTHERAPY

The revised edition of *Psychotherapy* by Dr James J Walsh contains four entirely new chapters and some other material It is a massive work containing an enormous amount of information, historical and other In a sense the book may be described as "old fashioned", the author makes the briefest references to psycho-analysis, he does not mention the various mental mechanisms and makes no attempt to discuss psychopathology as it is now commonly understood For Dr Walsh psychotherapy means suggestion in the broadest sense of the word, and his teaching is designed to show the importance of this process in the treatment of all forms of disease both functional and organic His outlook is perhaps best expressed in his quotation of Mandeville (fourteenth century) from Avicenna the Arab Galen of the eleventh century, who owed it to the ancient Greeks 'Often the confidence of the patient in his physician does more for the cure of his disease than all the physician's remedies" This quotation is printed on the title page and its spirit permeates the whole of the author's teaching He holds no exaggerated notions as to the possibilities of cure by suggestion in organic diseases, but he is no doubt correct in his opinion that all disease is favourably influenced or at least its pains alleviated by an attitude of faith and hope on the part of the patient

This book approximates to being a textbook of medicine because its author in accordance with his aim deals exhaustively with psychotherapeutic procedure in disorders of the digestive tract cardiac disease respiratory disease affections of the joints and muscle gynaecological disorders genito-urinary and skin disease and organic

nervous conditions, as well as the functional nervous disorders There is a great deal in the book which should recommend it to the medical practitioner, it is true that much which is now regarded as so essential for the effective treatment of nervous disorders is omitted, but at the same time a great deal of strictly practical advice is given which the family doctor will find very helpful, in some respects it may prove more helpful than some of the more "modern" works, the theories of which the practitioner is apt to find almost incomprehensible The book would perhaps have been more useful to the busy doctor if it had been considerably contracted, but the historical survey given by Dr Walsh is certainly interesting

SURGICAL OPERATIONS

The fourth edition of *The Student's Handbook of Surgical Operations*,[6] by Treves and Hutchinson, makes a very welcome appearance Although its new lease of life rests entirely in the hands of Mr Jonathan Hutchinson, it revives the memory of the distinguished author of the first edition Of its kind this book is a classic, a model of concise and literary description of operative procedure The increase in size is about forty pages, and the number of illustrations has grown to 167 New operations are substituted and those considered obsolete are discarded For instance, partial gastrectomy, operations for congenital pyloric stenosis, displaced semilunar cartilages, meningeal hæmorrhage, fractured patella, are now fully described, whereas Chopart's and Pirogoff's amputations pass into oblivion We could wish Mr Hutchinson had applied the axe with a heavier hand to this chapter Although the "classical" operations must of necessity exercise the mind of the student at examinations for want of better material, it seems that this section is too laboured with alternative methods The average student sees comparatively few of these operations in hospital, and their description certainly could be simplified in view of the experience gained during the war Nevertheless, Mr Hutchinson has moved in the right direction, and we feel sure the popularity of this excellent handbook will be further enhanced

NOTES ON BOOKS

We have received copies of two publications dealing with income tax In his little volume[7] Mr Ronald Staples, who pleads guilty to holding an official position in the department responsible for income tax administration, has addressed himself to the task of putting into brief and clear form sufficient explanation of the working of the system to enable the average taxpayer to surmount the difficulties of rendering returns, checking the claims made on his pocket, and getting back from the State what is due to him The little book is not without blemishes, for instance, the method of computing repayments shown in the useful chapter entitled "How to secure repayment" is obsolete and apt to mislead, and we differ from him in thinking that the chapter on inhabited house duty justifies its inclusion in spite of the recent repeal of that tax It is, however, clearly set out, and should be found very useful by the class of person for whom it was written Oliver and Boyd's *Tabular Views*[8] is, in the main, a statistical chart, setting out such details as the rates of income tax from 1842 onwards, the money value of various totals of allowances, etc, but contains also a useful section setting out the various allowances and the conditions attaching to them, and gives illustrations showing the rules in operation It is a triumph of ingenious condensation, but has the unavoidable defects of that quality it is not "readable," and covers the normal rather than the unusual case

The novel entitled *Dr Porteous*[9] is a posthumous work by the late Dr Arthur Brebner, the author of two other well written stories, *The Shadows of the Ship* and *Patches and Tornander*, who died of tuberculosis aggravated by war service a few years ago It is a record of the struggles of a young doctor in an uncongenial profession subsequently changed for that of an artist in which the future promises to be brighter

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

(*Continued from page 864*)

A further sitting of the Royal Commission on Lunacy and Mental Disorder was held on November 5th, under the chairmanship of Mr H P Macmillan, K.C.

Evidence of Masters of Poor Law Institutions

Evidence was tendered by Mr H Senior and Mr G Ushi on behalf of the National Association of Masters and Matrons of Poor Law Institutions Their principal contention was that a longer period of detention was desirable than the fourteen days allowed by the Act, the period they suggested was twenty eight days This longer period would enable the justice and the doctor to come to a more deliberate decision on the case, and possibly fewer cases would have to be certified Even as it was, it was found unnecessary to certify quite 50 per cent of the people who came in under temporary orders The witnesses also spoke of the unsuitability of small Poor Law institutions in rural districts for the handling of mental cases, owing to the inexperience of the officials, and they contended that in each considerable area there should be one Poor Law institution selected and equipped for the purpose of dealing with the cases The witnesses also felt that the medical officer should be given power to discharge the patient at any time within the detention period Cases of permanent detention should be subject to periodical revision by a medical officer in conjunction with a justice of the peace

The Judicial Authorities

Mr L Whitemore, J.P., a judicial authority under the Lunacy Acts for the County of London, gave evidence from his considerable experience in dealing with petitions for reception orders in the case of private patients He complained of an unnecessary duplication of authorities, and also suggested an intermediate period of observation before a final judgement was pronounced upon any case He was quite in sympathy with the views already expressed that a longer term to consideration was desirable before final certification either of a private or a Poor Law patient, but if this longer period were granted an additional safeguard should be provided in the shape of an order from the Board of Control

Colonel P Broome Giles, C.B., F.R.C.S., J.P., lately of Buckinghamshire and now of Folkestone, speaking as a judicial authority in lunacy, considered that it should be made obligatory on the magistrate to visit every patient who was the subject of an application for an order It was true that the justice had the medical certificates to go upon, but he was not doing his duty unless he saw the patient for himself It had been his own practice not to pay regard to the information contained in any document until after a personal interview He felt it to be his duty as a magistrate to make up his mind from the facts he discovered for himself The Chairman pointed out that the witness was in an exceptional position in that he was a qualified doctor as well as a magistrate, and asked what would be the duty of magistrates who had no medical qualification The witness considered that they must still use their own judgement, but, of course, in dealing with an alleged lunatic the information given on the certificates would be their chief guidance It had been his practice in some cases, when the patient was brought to him by a relative and he was not sure as to the nature of the case, to adjourn it for fourteen days for further consideration In reply to a question as to what would happen to the patient in the meantime, the witness said that if the patient's house was sufficiently large he would retain there, nurses being called in, and the man carefully watched, in some cases the workhouse was the only place for such reception, but it was not at all a proper place, and it was the duty of the country to provide houses of reception for such cases The Chairman said that it was a possible recommendation of the Commission that there should be places for the treatment of non certified cases but he thought it inevitable that the patient should be subject to some degree of control or compulsory detention during that interval

The witness was next questioned on his experience as a member of visiting committees, and was asked whether the visits gave patients in institutions a satisfactory opportunity of access to the outside world The witness replied that few complaints were made to visitors but few of them proceed to inquiry to be of a tangible nature No difficulty, in his experience, was put in the way of a patient interviewing the visiting magistrate He had given private interviews to lunatics in some cases in a locked room no other person being present Asked whether this was not rather a dangerous proceeding in view of any possible homicidal tendency on the part of the patient the witness replied that in doing so a certain risk must be taken, and personally he was one of a middle weight gloves in his earlier days and to be on the case of ill treatment had been brought to his knowledge

medical officer and the attendant dismissed In another case the complaint was brought by the patient and sustained, and a negligent attendant was dealt with

In reply to further questions he said that in his conversations with alleged lunatics preliminary to an order he was careful never to disclose the fact that he was a judicial authority Earl Russell asked whether this was quite fair to the patient, who finding a stranger appearing in the character of a friend, would never know when he had to fight an order The intention of the Act was that the justice should represent the public, and that the patient should thus be given a chance of making his protest The witness replied that persons in this state were very impressionable and the knowledge on their part that he was there as a magistrate with a view to their detention would upset them to such a degree as to make it impossible for him to arrive at their true condition Lord Eustace Percy asked to what extent a magistrate could be a check on the medical authority The witness replied that the magistrate had got the Act to administer and if he found nothing contrary to what the medical men had certified he was obliged to sign the order He added that he had only known one magistrate who went against medical opinion and he was one of that class of men who ought not to be magistrates This magistrate refused to certify a lunatic and within two hours the lunatic had seriously injured his wife and committed suicide The witness did not think that any magistrate would go against medical opinion but it was very necessary that the magistrate should personally verify as far as possible the facts stated on the certificate He himself always took steps to verify those statements on the certificate which were put down by the medical man as not having been observed by him but as having been obtained by hearsay evidence He thought that the verification of such information ought to be made obligatory on the justice He said, in reply to Sir Humphry Polleston that he had not found during recent months any particular indisposition on the part of private medical men to sign certificates

FUTURE OF MEDICINE AND HYGIENE IN THE TROPICS*

DR ANDREW BALFOUR'S ADDRESS

THE inaugural address at the opening of the Anderson College of Medicine in Glasgow was delivered by Dr ANDREW BALFOUR Director of the London School of Hygiene and Tropical Medicine The title of the address was "Vistas and Visions Some Aspects of the Colonial Medical Services" In it he drew a sketch of our present knowledge of tropical pathology, and endeavoured to awaken in his hearers a realization of the fact that for those of our somewhat overcrowded profession who are keenly interested in pathological research the tropics still furnish innumerable problems calling for solution

Dr Balfour continued Owing to the remarkable advances that have been made in our knowledge of tropical diseases in recent years, there exists perhaps, a tendency to regard this field of inquiry as having been worked out and consequently, as lacking in interest The reverse is the fact The discoveries already made have opened up new problems, and lacunæ in our knowledge retard in many ways their fruitful application Until comparatively recent times the coastal belt from the Gambia to the Niger bore an evil reputation as the white man's grave through the work of Manson and Ross that region has been transformed, and it might be supposed that we have little more to learn with regard to malaria Laveran discovered its cause Ross and others showed how the infection is conveyed and the Countess of Cinchon many years ago introduced its specific cure Yet thirteen years ago Professor Stephens of the Liverpool School of Tropical Medicine called attention to the following points on which our knowledge was defective (1) the presence of bodies of uncertain significance in the salivary glands of anophelines (2) the alleged transmission of malarial infection through the eggs of the mosquito (3) conditions determining the successful infection of anophelines fed on infected blood, (4) the number of persons that one anopheline can infect (5) the variation in the percentage of infected anophelines from month to month, and its extent (6) the duration of infection in an anopheline once infected, (7) the penetration of the red cell by sporozoites, (8) the properties of the salivary secretion of mosquitos Some of these problems have been solved Bruce Mayne has shown that one anopheline can infect as many as five persons, Wright has worked at the functions of the œsophageal diverticula, the contents of which mingle with the saliva, and Yorke and Macfie have carried out researches on the salivary secretion itself and have found that it does not contain a haemolysin As to the remaining questions, our knowledge is still defective, although Sinton seems to have confirmed Rowley Low's view that the sporozoites do not enter the red cells, but adhere externally to their envelopes

Again, yellow fever is a disease concerning which much has been learnt in recent years The Americans have solved the problem of its conveyance Noguchi has discovered its virus, the *Leptospira icteroides*, and a preventive vaccine and curative serum have been prepared Yet we have still much to learn regarding this deadly malady on the African West Coast We do not certainly know whether it is the same disease that once ravaged the ports of South America the West Indies, Bermuda, and the eastern seaboard of the United States Dr Carter of the United States Public Health Service is of opinion that it is of African origin but the leptospira has not yet been demonstrated in West Coast cases Moreover we do not know it more than one species of stegomyia or aedes acts as its vector in Africa, we are not sure if any of the lower animals serve as reservoirs for the parasite and we have great difficulty in distinguishing the malady from Weil's disease the spirochætosis icterohæmorrhagica, which not long ago played havoc in a Scottish coal mine Recently a discovery has been made by Hoffmann of Havana which if confirmed is of importance He has demonstrated the presence of lime casts in the kidneys of patients who have died from yellow fever, their occurrence is apparently, pathognomonic and will serve to distinguish yellow fever *post mortem*, from other febrile maladies associated with jaundice

To take another instance—bubonic plague This disease is at the present moment taking toll of human life on the Gold Coast, in Ashanti and in Nigeria Its pathology has been fully worked out the rôle of the rat and of other rodents has been established the flea has been incriminated, and there is a plague vaccine and plague serum What further knowledge can be required Yet plague persists it slays millions in India and the rat, its carrier, defies our efforts to cope with him plague serum is too often a broken reed and our drugs are usually powerless Rodier's method of killing all female rats caught and letting loose the males —a plan that has been successful in the case of Australian rabbits and used to good effect against rats in some limited areas—has been tried we have attempted to interfere with the animal's family life its fertility and fecundity, and, generally speaking we have failed We are only beginning to realize the importance of certain factors French observers have drawn attention to the possible presence of healthy human and healthy rat carriers of the disease It is obvious, therefore that in the group of British colonies referred to, and considering only three of the diseases met with in them, there is plenty to engage the attention of a keen and trained observer and it may be assumed with tolerable certainty that other diseases remain to be discovered—diseases which at present are mistaken for disorders with which we are more or less familiar and which have to be separated and worked out

To turn to another region—the Sudan Although the Sudan Medical Service is not under the Colonial Office the Anglo-Egyptian Sudan possesses a Government service well worth the attention of the young medical graduate It is many years since Sir William Leishman a Glasgow man discovered the protozoal parasite of the tropical malady, which is found in certain parts of the Sudan called, after him leishmania is and by the Indian kala azar or black fever We are still ignorant how the parasite effects a lodgement in the human body There is a fine field for work in this direction although we may conjecture that it is about to be explored with considerable thoroughness by Colonel Megaw and his companions in the Calcutta School of Tropical Medicine There is moreover, a new disease existing in the Northern Sudan which requires particular attention It is associated with the

*Abstract of inaugural address at the opening of the winter session of the Anderson College of Medicine Glasgow October 14th 1924

presence of a peculiar bacillus which Dr Andrew Balfour found in the throat and mouth of a British officer in Khartoum, producing ulceration and exercising a markedly depressant effect on the heart Owing to loss of the culture through no fault of his own, Dr Balfour was unable to pursue the study of the organism, but it has since been rediscovered by a Canadian medical officer while investigating an outbreak of sore throat among British troops in Khartoum With regard to sleeping sickness, which is a well known malady in Southern Sudan, although we know the trypanosomes which cause it and the tsetse flies which act as their intermediate hosts, and can cure many cases by atoxyl, antimony, Bayer 205, or tryparsamide, we are very far from having exhausted the subject of the old negro lethargy We are not yet certain whether *Trypanosoma gambiense* and *T rhodesiense* are one and the same parasite or different species, we still dispute over the question of wild animals as reservoirs of infection, we are uncertain as to the feeding habits of glossinae, and are still seeking for the best drug to use in the treatment of the disease

Nor in the adjoining territory of Uganda is there any lack of medical problems Plague, malaria, and sleeping sickness are rife in the protectorate, and cerebro-spinal meningitis continues to take toll of the natives Syphilis is one of the curses of the country, and despite all that has been accomplished in working out its etiology and pathology, there is still much to be discovered, especially in relation to its ravages among the natives and the life-history of the parasite Another spirochætal disease prevalent in Uganda is tick fever, and it may be said with regard to spirochaetal diseases generally that we are still in the dark as to the morphology and development of the organisms that cause them In Kenya plague again presents its problems, and in addition there occur there a strange complaint simulating pneumonic plague, and a malady recalling typhus fever, but apparently not louse-borne, both of which require elucidation, in this region there is also the important and deeply interesting question of the acclimatization of the white settlers in the highlands The Germans have worked hard in Tanganyika Territory, but have by no means exhausted its possibilities for the British student as a field for inquiry There is leprosy, for example—we remain ignorant of its mode of spread, despite theory after theory, and tuberculosis, too common in the coastal towns, it would be very far from the mark to suppose that tuberculosis is a completed chapter in pathology and therapeutics, especially if regarded from the tropical standpoint Dysentery is also common in both forms in Tanganyika, and far from the war having taught us all we need to know about that disease, it served rather to show us how ignorant we are on the subject So far as bacillary dysentery is concerned there are undoubtedly facts to be unearthed regarding its relation to flies In some places there is very little dysentery when flies swarm, the infection is there but the flies do not seem to act as carriers Nor can it be affirmed that we have reached finality in the treatment of chronic amoebic dysentery, and the man who discovers a cure for that disease will earn the gratitude of many a hapless sufferer

Rhodesia, the youngest of Crown colonies, presents new subjects for inquiry At the present moment Northern Rhodesia is disturbed by the occurrence of cases of splenic abscesses among the natives, the etiology of which so far remains obscure, and in Southern Rhodesia blackwater fever is attracting much attention Even if we admit that the latter is intimately bound up with malaria, we have yet to learn the precise relationship and how really bad cases fall be— There is, it may be said, little to be brighter for fault of an artist We thought we knew all ——lulant fever, since Bruce, the *Micrococcus melitensis*

[1] *Student's Handbook of Surgical Technique* By Frederick Treves Bt CVO CB LL Fourth edition Pp xvi+1024 (Cr 8vo) London Cassell and Co Ltd 1924 (Cr 8vo pp xvi+582) Bevan in Southern Rhodesia Tax By Ronald Stark Third edition Pp 128 London Tindall and Cox 1924 (Cr 8vo pp 128) Tables for Income Tax and Super Tax Edinburgh Oliver and Boyd Price 1 Income Tax By Arthur Brebner London Pitman (Cr 8vo pp xii+240 7s 6d net)

in miniature, the finest and smallest of British colonies Its disease furnish food for thought apart from those already mentioned Why is it that yaws does not occur there? Its disease is first cousin to syphilis, and yet it is not a venereal complaint It has undoubtedly been introduced into Mauritius, but it has not spread Why has cholera, the water-borne disease *par excellence*, which has played such havoc in the island on several occasions, disappeared from it entirely, although to all appearance there was everything in favour of its continuance and extension? Why has the chigger flea which burrows into the skin of the feet, never gained a footing in the colony? In Ceylon we may ask ourselves how we stand with regard to sprue, that malady of frothy stools, sore mouth, emaciation, and anaemia, which hurries many a tropical sojourner to the grave If Scott is right—and there is good reason to credit his findings as regards calcium metabolism and the control of the parathyroids—one puzzle will have been solved, but even so there are points about sprue that will still require investigation The hookworm also causes much mischief in Ceylon, and although, thanks to the Rockefeller workers and others it has been tracked and can be treated, we have yet to learn definitely the nature and action of its toxin

Passing on to Singapore and the Malay States, we greet a worthy son of Glasgow, Sir Malcolm Watson, a household name in Malaya, whose energy, pertinacity, and enthusiasm in antimalarial work have saved many thousands of lives Malaya has a fine record of research and the practical application of results but if we take beri-beri as an instance it is safe to affirm that we have not heard the last about that disease, either there or elsewhere It is possible that more than one disease masquerades under that name Diet deficiency, the lack of antineuritic vitamin, will explain much, but it is doubtful if it will explain all There may be a toxic factor, it present merely suspected and remaining for definite elucidation Malaya well exemplifies our opportunities, for it was only recently that Stanton and Fletcher determined the cause and worked out the pathology of what they called melioidosis, formerly described by Whitmore as morphine injector's disease

It is possible that there are no more fruitful fields of research than are to be found in Borneo and New Guinea Passing these over, however, we find the South Sea Islands presenting many problems of pathological interest Here we are faced by the mysteries of filariasis Bancroft and Manson first shed light on the life-history of the blood worm, and Low completed the tale That is an old story, yet the disease remains incurable, save where the surgeon's knife can give relief In Fiji we have yet to learn why the island is practically immune from syphilis, and how best to prevent the extinction of a fine race, decaying under the influence of a civilization that is alien to its sentiment There is work to be done in those islands, and although Dr Buxton has it well in hand at the present time we may be very sure he will leave something for his successors to accomplish Filariasis will be met with again in Demerara, but, in addition, epidemics of dengue will from time to time occupy the attention Dengue, dandy, or breakbone fever is one of those partly explored diseases as to the cause of which we are still somewhat uncertain, although there seems little doubt that a blood spirochæte is to blame, as is the case with the very similar sand-fly or phlebotomus fever common in Palestine and Mesopotamia Do we know the cause of pellagra, which will be met with in the Leeward and Windward Islands? Though there is little doubt of its being a dietetic disease we are not yet certain of its precise etiology, notwithstanding the valuable work of Goldberger Can we say why Barbados is free from anopheline mosquitos? Is it wholly attributable to the presence of the tiny larvivorous millions fish? It seems doubtful Why is Bermuda free from mopheliines? What do we know about the peculiar form of peripheral neuritis met with in Jamaica? Very little indeed And so it is wherever we cast our eyes—everywhere a burden of disease, everywhere work to be done So far from the interest in tropical research having been exhausted, it may be truly said that the earth is literally encircled with unsolved problems awaiting their solution at the hands of the younger scientists of our generation

British Medical Journal.

SATURDAY, NOVEMBER 15TH, 1924

MEDICINE A SCIENCE

When Boerhaave (1668 1738) called Sydenham (1624 1689) the British Hippocrates he intended not a mere general compliment but a discriminating judgement He meant that Sydenham had revived and sympathetically employed the methods of the Father of Medicine Nor is it a mere compliment to call Hippocrates by that title Doubtless in its primitive beginnings medicine was an art with magic for its sister but since Hippocrates it has been a science with its own methods and as the Regius Professor of Medicine at Oxford pointed out in his Harveian Oration (British Medical Journal, October 25th, p 747) it is the mother of the sciences

Ever since the renaissance of learning there has been an indisposition frankly to admit that medicine is a science of itself At the time of Sydenham as Sir George Newman has well said the equipment of the medical man was classical he was drilled in the traditions of Aristotle the aphorisms of Hippocrates the doctrines of Galen and the canon of Avicenna but of systematic clinical observation and instruction there was none The only direct contact with nature in the curriculum was for the majority, through botany, for the few through anatomy also and for fewer still through physiology Harvey, not being satisfied that medicine should confine itself to observation and the method of trial and error in the human patient insisted on the need for seeking out the secrets of nature by way of experiment By so doing he founded physiology but not many in his own or the succeeding generation understood

On the other hand, there has been since the middle of the nineteenth century, a disposition to deny autonomy to medicine for other, and it might also be said converse reasons It has had to endure the allegation that it is not a science of itself, but is no more than an art dependent for its advance on other sciences—on chemistry and on biology, including bacteriology and parasitology but especially on physiology which claims insistently to be an independent science supplying the practice of medicine with facts Sir Archibald Garrod referring to this matter in the Harveian Oration, spoke wisely and aptly but the subject might with advantage be more fully developed by some future orator The time seems ripe for we are witnessing a linking up of the laboratory with study at the bedside While commending the tendency of many young workers imbued with the scientific spirit to elect to follow the path which leads through the laboratory Sir Archibald Garrod deprecated the disposition which undoubtedly exists among some of them to look down on the clinician forgetting that clinical medicine can and should be pursued in the scientific spirit it presents immense fields for scientific research which must be conducted in accordance with certain special methods peculiar to itself it is not only the mother of the sciences but itself one of them

Sydenham entered on the study of medicine at a time when it was dominated by the authority of the ancients and by speculations founded on various preconceived theories He went back to the bedside to observe as Sir Humphry Rolleston puts it the natural history of disease Both Dr Arnold Chaplin in the contribution he makes to our columns this week and Sir George Newman in the thoughtful and entertaining essay (p 922) he has published for the tercentenary, ask us to believe that Sydenham's Puritan breeding and upbringing had much to do in determining his attitude towards medicine It may be so but it was a time of mental questioning and unrest in politics as well as in science and religion At any rate circumstances of heredity and environment had prepared Sydenham's mind to understand and apply the Hippocratic doctrine and method That he did so to the great advantage of medicine at a critical moment is his great claim to remembrance we can afford to forget that in his singleness of purpose he did not attempt an integration which is only now being brought about and that he disregarded the new knowledge Harvey and his successors were rapidly accumulating around him It detracts from his glory, but it may have been all to the good in the long run

THE GENERAL PRACTITIONER AND THE MATERNITY SERVICE.

However harassed and long suffering he may be the general practitioner is not as a rule inarticulate and has many ways of making his voice heard It is therefore difficult to understand why he has remained apparently oblivious of the storm that is now raging over the shortcomings of the maternity service—a service in which he plays a leading part

This Journal cannot be blamed for not giving full publicity to the matter frequent articles and notes have called attention to it Four weeks ago a leading article announced a joint meeting at the Royal Society of Medicine, of the Obstetrical and Epidemiological and State Medicine Sections with the Society of Medical Officers of Health, to be held on November 6th to consider the notification of puerperal sepsis and other kindred questions That article in our issue of October 18th contained a special invitation from the Council of the Obstetrical Section to general practitioners to come and express their views and, in order to make clear the problems for discussion and how those engaged in midwifery practice might be affected a retrospect was given of the various papers and abstracts that had appeared in our columns The proceedings of that meeting are fully reported this week at page 900 and attention may be drawn to the fact that apart from the one speaker announced to present the point of view of the family practitioner—the branch of the profession most concerned—there was no audible response to the invitation The report of the meeting may serve as a text to urge the immediate need for discussion of the official reports and their recommendations by all Branches of the British Medical Association so that the views of its members may carry due weight Only by mature consideration and full discussion will it be possible for the Association to express the views of its members

Like other Government publications the report from the Ministry of Health (No 25) by Dame Janet Campbell and that of the Departmental Committee of the Scottish Board of Health are read and studied by those of the general public interested in health matters These reports have already prompted questions in Parliament to the Minister of Health and have stimulated conferences such as that reported in

our issue of October 11th (p 685) in which the public take part, showing that there is now a body of opinion that will press politically for immediate action by the central and local health authorities Circular 517, issued by the Ministry of Health to local authorities, *urging the adoption of measures to reduce the risk* in childbearing, is further proof of official movement

The discussion at last week's joint meeting had its origin in a request from the Ministry of Health for advice *from the Obstetrical Section* as to what administrative action might be taken to reduce the incidence of puerperal sepsis, and particularly as to the measures that should be taken to lead to its prompt notification *The feeling of the meeting* seemed to be that, though notification, to be effective, must include early and suspected cases—for example, those with a temperature of 102° or over, continued for twenty-four hours or accompanied by a rigor—so wide a form of notification is useless at present because of the impossibility of providing facilities for further observation of the patient, for accurate diagnosis of the cause of the fever, and for treatment It appeared to be felt also that a more thorough survey of the maternity services in the country is needed, particularly in regard to the organization of specialist services and better hospital provision On this account the setting up of a Royal Commission or other method of exhaustive inquiry was strongly advocated Though the discussion may have had little in the way of definite result, it revealed the difficulties with which the question bristles, and the opportunity may be taken to remind the profession as a whole of the various proposals put forward in official reports and elsewhere, all of which need careful consideration

Besides a more thorough system of notification of puerperal fever, investigation by the local health authority of all deaths in childbed or deaths within four weeks of the termination of a pregnancy is proposed in the Scottish report, and to aid in this it is suggested that there be added to the birth notification form a line giving the name of the person present at the birth and responsible for the delivery (whether doctor, midwife, or nurse) In some of the conferences on the subject it has been urged also that power should be obtained to conduct *post-mortem* examinations on all deaths in childbed As will be seen from our report of the

the subject So[illegible]ng at the Royal Society of Medicine, Dr there are undoubtedly presented the general practitioner's its relation to the made clear the importance of deciding dysentery when flies were of investigation into childbed flies do not seem to in the hands of the larger or the [illegible] one meeting we have thorities These investigations and Flemming, whic[illegible] dysen public assistance should surely be point of view, [illegible]t disease councils and the councils of county whether the per[illegible] delegated to the smaller sanitary deaths should be [illegible]ungest[illegible]on done in the case of the Mater- smaller health auth[illegible]y Act The less parochialism the organization of [illegible]ed by the native outlook upon the provision for reserved to county [illegible]id in more efficient are these services boroughs, and not [illegible]much the method of reviewing the authorities, is has be[illegible]timately nity service, and of deciding nity and Child Welf[illegible]precise led and how it can best be and the wider the o[illegible]. There lv ntages in the appoint maternity ser[illegible]ices, the first [illegible]. W[illegible]rather than the che[illegible]per likely to be As to t[illegible]ul Committee With its present state of the mate[illegible]urgent the[illegible]nd not merely a report where amendment is need[illegible]enlarged effected there are many [illegible]l Commission offers ment of a Royal Commissio[illegible]hird [illegible]greed decisions and less effective Departmen[illegible]ry Committee powers of printing evidence [illegible]Session and [illegible]s subject will be recommendations a Roy[illegible]ral practitioners great [illegible]portunities for arriving

of the country to a realization of the necessity for immediate consideration of all aspects of the problem of the reduction of maternal mortality in childbed Their case must not be allowed to go by default To wait until public opinion has so far crystallized into administrative action that it has become difficult to mould would be most unfortunate, alike for the general practitioners and for the public health Their co-operation must be an integral part of all schemes for the betterment of the maternity service Provided discussion is carried on from the wide viewpoint of the public good, and not from the narrow one of professional interest, the reasoned opinion of those who have hitherto borne the burden of the maternity service is the most essential element in bringing about wise amendment

THE NEW MINISTER OF HEALTH

Last week we urged the importance to the nation of the appointment at the present juncture of a strong Minister of Health, and by the time our plea was published the announcement had been made that Mr Baldwin's choice had fallen on Mr Neville Chamberlain That selection exactly meets the case We believe that Mr Chamberlain's brief tenure of the same office in 1923 impressed the staff at Whitehall with his high qualifications as their chief, and his work on housing commended him to the country generally One fact which has been divulged regarding his appointment possesses a special significance He was offered the higher post of Chancellor of the Exchequer, but declined it in favour of the Health Ministry A man who can make a sacrifice like that for an ideal will go far in the sphere he has deliberately chosen He appreciates its possibilities, and will surely turn the possibilities into actualities The safety and security of the kingdom largely depend on the solution of the housing problem That, evidently, is the first task to which Mr Neville Chamberlain will apply himself, and his success should go far towards establishing peace and contentment throughout the land But also, as indicated last week, we trust he will find time to tackle and reform the whole system of local government in England Constructive statesmanship in these two directions would give him a great place in the history of our times

THE METHOD OF PRESENTING SCIENTIFIC COMMUNICATIONS

The enormous growth of modern scientific literature is no doubt, alarming—eight journals, for example, are regularly appear on the subject of cancer research alone—and the scientific student will soon have to develop a protective mechanism against the multiplicity of papers with which he is supposed to keep pace We are not sure, however, that the method suggested by Dr J A Murray in his recent presidential address to the Pathological Section of the Royal Society of Medicine quite meets the situation Dr Murray traces the traditional form of the scientific paper to the thesis required in Continental universities of candidates for doctorates in medicine and science All such theses contain long verbal descriptions including a laborious summary of existing literature, and it has been taken for granted, even in this country, that is the proper form for a scientific communication, though it takes up a great amount of printed space and makes heavy demands on the time of the reader Dr Murray also said, quite truly, that the art of writing a narrative is one which few people acquire, and that in scientific work in particular—say, the description of pathological experiments—it is hardly to be expected Meanwhile the verbiage grows apace Dr Murray's

tion is to fall back frankly upon a pictorial method of presentation After all, our written or printed characters have been developed from the primitive picture writing, although to day they appeal to the eye only by association through the medium of the memory for sound In some respects already the pictorial method of presentation has been adopted, as witness the kinematograph, which, with a minimum of words or no description at all, can convey the details of a scientific process A number of medical or scientific films have been produced, but this method, of course, is far too laborious for the man who has new work to communicate Dr Murray's idea is to use photographs sketches, diagrams, and symbols, liberally interspersed in the minimum of text He thinks it possible to convey in a rough sketch some details which would require a page of more of written description To illustrate his contention he "read" a paper through the episcope on some experiments in mouse cancer The paper ran to about half a dozen cliches, with various drawings, diagrammatic conventions, and a few necessary words on each Perhaps it is a little unfair to say that, although protesting against the use of many words, he spent half an hour of excellent talk in developing his idea, and a further half hour of equally excellent talk in explaining his sketches We imagine that, block illustrations being more costly than type, the widespread adoption of a pictorial method would be a serious matter for the publisher, and we are not sure that it would even attain the end in view for words, cumbersome as they are, have a certain precision, whereas pictures may lend themselves to a variety of interpretation, and thus obscure rather than elucidate the theme If scientific writers cannot master the art of brevity, the only hope appears to lie in the development by the scientific public of a capacity for rapid assessment and discrimination

CONGRESS OF OBSTETRICS AND GYNAECOLOGY

The fifth Congress of Obstetrics and Gynaecology will be held in London at the house of the Royal Society of Medicine, from April 22nd to 24th, 1925 The first congress was held in London in 1920 subsequent congresses met in Birmingham, Liverpool, and Edinburgh The purpose of the congress is to bring together members of the various British and Irish societies devoted to the subjects of gynaecology and obstetrics It includes the Section of Obstetrics and Gynaecology of the Royal Society of Medicine the Midland Obstetrical and Gynaecological Society, the North of England Obstetrical and Gynaecological Society, the Edinburgh Obstetrical Society and the Section of Obstetrics and Gynaecology of the Royal Academy of Medicine in Ireland Dr H Russell Andrews will preside over the congress next year in his capacity as President of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine The programme of business will include a set discussion on the diagnosis and treatment of puerperal sepsis, which is expected to occupy one whole day of two sessions This discussion will be introduced by a report upon which a special London committee has been working for more than a year already, and another report is expected from the North of England Other sessions will be allotted to the reading of individual communications and to episcopic demonstrations on histological subjects and a preliminary report on eclampsia will be communicated by the Special Eclampsia Committee Operative demonstrations will also be given at the various hospitals by their gynaecological surgeons and an exhibition of pathological specimens will be arranged Notice of intention to read papers should reach the honorary secretaries, Dr Clifford White 62 Harley Street W 1, and Dr J D Barris 50, Welbeck Street, W 1, before December 31st and the papers should be in their hands by February 28th 1925 It is hoped to publish in advance a short extract of each paper accepted by the congress committee Communications respecting papers should be addressed to the honorary secretaries of the congress and those relating to the exhibition of specimens to the honorary secretary of the Pathology Subcommittee, Dr Eric Gerard Williams, 5 Wimpole Street, W 1 The London members of the congress will entertain the visiting members at lunch on April 22nd, and the President will hold a reception in the rooms of the Royal Society of Medicine the same evening On April 23rd the members of the congress and their guests will dine together

INTELLECT AND POSTURE

Dr W Colin Mackenzie, well known to orthopaedic surgeons as the author of a treatise on the action of muscles has issued a neatly printed booklet to support a bold and somewhat novel thesis[1] He believes that the impetus in development from the reptile to the highest mammal is improvement in muscle function culminating in the erect posture" In another passage he amplifies his meaning by the following comparison 'If we examine anatomically the body of the lowest mammal (echidna) with that of the highest mammal (man), we find little difference between them The general structure scheme, in spite of the millions of years intervening is the same We have in both a four-chambered heart, complete respiratory piston or diaphragm big spleen lungs similar and confined to the chest and the grey matter of the richly convoluted brain of both is external and not the white as in the reptile's brain Furthermore if we examine the organs microscopically we find the same structures as in man" "What then" asks Dr Mackenzie constitutes the great difference" His answer is The great difference between the lowly echidna and us is actually a muscular one We have the erect posture and it has not And that is really what I meant by higher mammalian evolution' For Dr Mackenzie posture maketh the man If we can explain how he has come by his posture then we shall have solved the origin of his brain and body This is a thesis which will require much fuller proof than Dr Mackenzie has succeeded in bringing forward in his present work On the other hand everyone must feel a real sympathy for the object which has prompted Dr Mackenzie to write this book When he returned to Australia at the end of the war he resolved to devote his life and resources to the study and preservation of the living fossils" of his native land —platypus, echidna and the many forms of marsupial— all of which are threatened with a speedy extinction He has set up an institution to carry out his aim and the proceeds of this book are to be devoted to it He reminds his readers that John Hunter was the first anatomist to study the archaic mammals of Australia and he proposes to follow Hunter by making function rather than structure the main end of his inquiry Our animals he writes 'are teeming with points of scientific interest In them the complexities of the human body are revealed in their simpler form A study of them is really a study of living human embryology—that is embryos in which we can study not only function on which structure depends for to the medical scientist the latter must be regarded as the register of the former It can be truly said that there is no problem in human anatomy or physiology on which a study of these animals fails to throw light As far as possible we have allowed Dr Mackenzie to speak for himself In the brief pace at his disposal in the present work he has been obliged to touch his theme lightly allowing matter to serve as evidence but we expect proofs will be forthcoming in full measure

[1] Intellect and Deviation to the Erect Posture By William C Mackenzie MD FRCS Director of the National Institute for Health Australia Foreword by Major Allan Graham [illegible] (Percy [illegible] 6d net)

THE FUTURE OF THE RONTGEN SOCIETY

SIR OLIVER LODGE relinquished the chair of the Rontgen Society on November 4th, and inaugurated his successor, DR W. E. BARCLAY of Manchester. The retiring president had some interesting philosophical observations to make on the subject of incredulity, both scientific and popular. The disbelief of some scientists—not, he thought, the most eminent—in the existence of the ether, the very ripples and vibrations of which lighted their path to knowledge, led him to consider the naturally sceptical habit of the human mind in general. He had known persons who disbelieved in the telephone, and who thought that x-ray photographs were in some way faked. Why, indeed, did people ever come to believe in certain things at all? Not because they understood them. Very few things in the universe were understood. The nature of almost everything, including the x rays and such forces as gravity and cohesion, was still a closed book. But things were believed simply because they became customary, familiar, and available. Sir Oliver Lodge added that such belief as was possessed required to be constantly fortified by fresh experience. He hinted that even a belief in the positive results of psychical research depended upon continuous discovery, unless fresh evidence was forthcoming, the evidence already gathered tended to evaporate. It was easy to see things one day, but after a time to doubt whether one had seen them. Sir Oliver Lodge looked forward to amazing new conceptions in physics resulting from the discovery—only just missed by Crookes—of the pressure of light. Infinitesimal as this pressure was, he said that it must be of immense cosmic importance, sweeping the universe of dust and inflating the biggest stars like footballs. Dr. Barclay's presidential address, which followed Sir Oliver's valedictory, ranged nearer home. He traced the history of radiology since the day, nearly thirty years ago, when the British Medical Association appointed a special commissioner to investigate "the application of the new photography to medicine and surgery," and dwelt especially upon the growth, separations, and fusions of radiological societies. Looking through the *Transactions of the Rontgen Society* during recent years he gained an impression that, taken as a whole, the proceedings had tended more and more towards pure physics, sometimes scarcely coming within the scope of the society's work as originally outlined. In view of the fact that out of the society's membership of 370 fully half were medical men, it did not appear that a proper balance between medicine and physics was maintained. Incidentally he found it interesting to note the contrast between the physical papers of the early years and those of the present day. Whereas the old papers seldom contained formulae, to-day formulae were so much to the fore as to suggest that to physicists they had become a dialect. Medical members, who did not know the dialect, were made to feel very illiterate, although, to be sure, a medical man had no right to criticize these things in view of the ancient convention whereby prescriptions were still written in Latin. But was the society bringing its medical members into touch with the scientists and others on whom there were dependent? Judging by the attendance of medical members at the meetings he feared that it was not, and that it was tending more and more away from the basis laid down by the late Professor Silvanus Thompson, as reported in the BRITISH MEDICAL JOURNAL in 1897, that of focusing the interests, in relation to x rays, of medicine, physics, and photography. Physics on the one side and medicine on the other had become so widely separated that very few medical men had been able to keep pace with the advances in physics while the medical problems were quite out of the beat of the physicist. The true function of the society lay on the borderline between the two, but to keep strictly to that line would mean that while the majority of the medical members were almost out of their depth, the physicists would be bored by the elementary character of the discussions. The establishment of the British Institute of Radiology (which was the subject of an article in the BRITISH MEDICAL JOURNAL of November 8th, p. 871) presented, he thought, a solution of the difficulty. This institute, an almost purely medical body, was anxious to join forces with the society. The fusion would enable the society to further the study of radiations in all their applications to medicine and the sciences and art. He asked whether the society was content to go on as at present, fulfilling a certain limited function to its eminent satisfaction, hugging a bank balance as a sickness insurance policy or possibly as a burial fund for which the Prince of Wales, at the last dinner of the Royal Society of Medicine, called a "learned corpse." Or was it prepared to empower its executive to take whatever steps were necessary, without endangering the society's individual identity, to extend its sphere of usefulness by direct fusion with the institute or by something short of that? Only by some such departure, so far as he could see, was the society likely to fulfil the objects laid down at its foundation in 1897—to promote the study of x rays in all its aspects. It is not customary to have any discussion after a presidential address, and therefore it remains to be seen how this proposal will be received.

THE CLIMATE OF THE ZOO

IN our issue of October 18th (p. 714) DR. N. B. LUCAS contributed an article giving notes of a careful series of observations, extending over four years, on the influence of the London climate on captive animals and on man—the animals in the Zoological Gardens in Regent's Park, and the human population in the borough of Marylebone. The effects of weather on health is a subject which has always been of medical and general interest, and has from time to time been dealt with by doctors and meteorologists, sometimes in combination, as in a research carried on by Mitchell and Buchan in Scotland many years ago. The results have not always been commensurate with the labour expended on inquiry, but that is owing to the inherent obscurities of the facts. So many influences operate in producing a given effect that it is particularly difficult to work back from effect to causes and to disentangle and measure the part played by each agency supposed to be involved. In no sphere of investigation is it more important to have an abundance of data on which to base conclusions, and Dr. Lucas is performing a service to science in extending research into the field of comparative biology, by comparing the influence of climate and weather on the mammalians of the Zoological Gardens with that of the human mammalians who make up the population of the area in which the gardens are situated. Manifestly there is one fundamental difference between the two groups. The inhabitants of the Zoo are, for the most part, in a foreign country, the human inhabitants of the borough are at home, in their natural climate and surroundings. In his study of the subject Dr. Lucas has brought together the four years' monthly facts regarding maximum temperature in the shade, mean minimum temperature of the air (not on the grass), atmospheric humidity, rainfall, north-east winds, sunshine, and fogs, in their bearing on mortality. He finds that the figures of deaths and of atmospheric temperature do not correspond when duly examined, though deaths are fewer in the warm summer months than in the cold winter ones. Rapid changes in temperature from day to day, even a drop of ten degrees in twenty-four hours, seem to have had absolutely no effect on the animals, as [illegible]

points out that this is not surprising, seeing that in the semi-tropical parts of the world the daily range of temperature is far greater than here Leaving out temperature, therefore, he proceeds to consider the influence of rainfall, humidity, and direction of wind Here, contrasting very opposite conditions which have existed as between February, 1921 and January, 1922 he holds that the data constitute a nearly perfect example of the importance for health, of a reasonably dry atmosphere Another contrast, involving factors of wind—north to east—rain and sunshine, is found between December, 1920, and October, 1922 The differences are adduced to support the argument that rain without cold winds is harmless, and the converse also applies That conclusion brings to mind the urgent advocacy, by Dr William Gordon of Exeter of avoiding localities under the influence of wet winds in selecting sites for the erection of sanatoriums for tuberculosis Log has been found a factor of little moment in Regent's Park there having been only forty one foggy days in the four years On the other hand the value of sunshine is now universally recognized and is illustrated in respect of the low human and mammalian death rate in the remarkably sunny year 1921, though in November and December Marylebone had an exceptionally high death rate both from all causes and from pulmonary disease Dr Lucas's provisional conclusions are, first, that neither a dry nor a warm moist atmosphere is harmful but a cold damp atmosphere is most deleterious both to the higher and the lower animals secondly that sunshine is beneficial to both, but apparently more lasting in the case of the lower mammals Though the four years' study must have involved much care and attention, the deductions from the facts are, as Dr Lucas realizes, only provisional, and the hope may be expressed that he will continue his observations in what, so far as we are aware is a fresh field of study in comparative biology and pathology

CANCER AND INFECTION

A CORRESPONDENT who has given much attention to this aspect of malignant disease writes The problem of cancer growth has been attacked from many sides during the last quarter of a century, and although the position is still untaken to use a military metaphor it is in fact being steadily sapped, and there seems more certainty of its fall *to-day than could have been claimed a few years ago* The characteristic habits of the cancer cell have been elucidated, and the history of its parasite like life has been written The solution of this part of the problem is in debt chiefly to the embryologists and the cytologists We know that cells of the soma may become free of the control under which they normally live, and that the essential features of cells so released are a reproductive activity similar to that of germ cells and a power of nourishing themselves without the aid of any coferments such as are necessary for the maintenance of normal somatic tissues Possessing these qualities the cells of cancer multiply indefinitely and infiltrate With many details left out, this is the manner of life of the cancer cell, of its birth however our knowledge is far from being precise We do know that it may be born from a somatic cell under the influence of a variety of stimuli The list of such stimuli is already long mere mechanical irritation, certain chemical substances (tar soot paraffin), x rays, and radium The cells of the epidermis may assume cancerous characters under the influence of any of these stimulants With regard to cancer of the internal organs it has been shown by Fibiger that cancer of the stomach may be experimentally produced in rats and in mice by feeding with the *Spiroptera neoplastica*, a nematode which infests the cockroach in its larval stage None of the stimulants in this list can be the activating agent in internal cancers in the human subject, but the fact that they are efficient agents in the production of the cancer cell is presumptive evidence that a stimulant of analogous sort is responsible for the cancer revolution in the internal organs such as the breast and the bowel If the proposition is accepted that a stimulant of foreign origin can start the cancer process in epidermis and mucous membrane it is worth while seeking for evidence of the presence of some foreign stimulating agent in for example, cancer of the breast If this be admitted, the first step will be the review of the work of those who have already reported the finding of organisms of a parasitic type in cancerous tumours The "parasitic theory" of cancer in the crude form in which it has sometimes been stated has resulted the orthodox pathologist and parasitologist the morbid anatomy and the pathology of the disease being so far removed from the reactions of the body to known parasitic infections The part which stimulation of somatic cells has been shown to play in the initiation of epidermal cancer forces attention anew to the question whether irritation or stimulation by parasitic infections of some sort may not be among the influences capable of transforming the somatic cell into the cancer cell The list of those who have published the discovery of parasitic organisms in cancerous tumours is long Among the most prominent are Doyen in France, Sanfelice in Italy, Gaylord in America In this country Pansell, and subsequently Plimmer, alleged the presence of "parasites" on histological evidence Morrant isolated an organism from cancer of the breast described its life cycle and demonstrated that it set up proliferative lesions in the guinea pig and the dog Ford Robertson described cultures of organisms derived from mouse cancer which he considered protozoan Lewton isolated from sarcomata a streptothrix which produced sarcoma-like growths in rats and lastly, Dr James Young has returned to the attack and related the isolation of organisms belonging to the vegetable kingdom with a peculiar and characteristic life history Parasitologists have dismissed these many independent reports as cytological errors and contaminations In view of our present-day knowledge of the relation of stimulation to cancer production the subject of the possible part played by parasitic invasion deserves an open minded reconsideration and investigation

RHEUMATIC FEVER IN THE SERVICES

At a meeting of the War Section of the Royal Society of Medicine on November 10th, Surgeon Commander T B Shaw, R N, brought forward some figures showing the incidence of rheumatic fever in the Navy From 1907 to 1910 the case ratio per 1,000 rose gradually to 8 53 and in the subsequent years *down to* 1915 *declined* to 6 3 then came a gap in the records owing to the war but in 1921 the figure fell to 2 28 and by 1922 to 1 95 A striking fall was found also in those conditions including chronic rheumatic affections, which came under the heading of diseases of the organs of locomotion the case ratio per 1 000 in 1914 was 14 25, in 1915 it was 20 75 and in 1921 it had fallen to 9 32 In the pre war period the incidence of rheumatic fever was highest on the home station, and lowest on the Mediterranean and the East Indies stations This might seem to confirm the general belief that rheumatic fever was more prevalent in the British Isles than elsewhere but the returns for the home station included those for boys' training establishments, which contained a number of subjects specially prone to the disease Rheumatic fever, from the service point of view was important chiefly for the heart lesions caused and the final invaliding which resulted The ratio per 1,000 invalided out for organic disease of the heart during the years of this survey showed no such reduction as appeared in the rheumatic fever incidence, and was more or less a constant figure Surgeon Commander Shaw thought it important in this connexion to have regard to the incidence of disease of the teeth,

gums, palate, fauces, and pharynx, where the case ratio per 1,000 in 1915 was 23 3, and in 1921 had fallen to 10 5, a similar decrease to that shown in rheumatic fever In the Navy increasing attention had been given during the years under review to oral hygiene and dental treatment, and although the causal agent of rheumatic fever had not yet been determined, it seemed likely that oral hygiene played an important part in prevention Greater attention was also given to environmental conditions, the men were protected as far as possible from damp and from exposure to sudden changes of temperature, and this again might account in part for the decrease in the number of cases of rheumatic fever In the case of boys particularly every effort should be made to maintain the tonsils in a healthy condition, and affections of the throat should be regarded more seriously than in the past Youths who complained of growing pains should not be dismissed too lightly, they should at least be excused all drills and exercises and ordered complete rest in bed Colonel J C Kennedy followed with some comparative figures for the Army Here also there has been a distinct fall in the rheumatic fever incidence For the period 1908-12 the case ratio per 1,000 was 5 9, in 1913 it was 4 3, and in 1921 it had fallen to 2 1 These were statistics for the whole Army, at home and abroad, but the drop was more striking if the United Kingdom alone were taken In 1913 the incidence of rheumatic fever per 1,000 in the United Kingdom was 5, and in 1921 it was 1 6 Of the home commands in the latter year London showed the highest incidence (5 4), the Eastern Command was next (2 4), the Southern, Western, Aldershot, Scottish, and Irish Commands ranged from 1 7 to 1, and the Northern Command was 0 8 The bad eminence of London might be put down to the old-fashioned barracks accommodation, and fog might be a contributing factor Among garrisons abroad the highest incidence in 1921 was on the Rhine and in Silesia (3 6) next came India (3 1), and Egypt and Mesopotamia (1 9) The figure for India was only slightly less than the figure in 1913 (3 8), although in the years 1904-7 rheumatic fever was comparatively rare in the Indian garrison—something like 0 8 per 1,000 The case ratio of tonsilitis had actually increased in the Army from 22 in 1913 to 32 in 1921 Squadron Leader E W Craig gave some figures for the Royal Air Force, which showed that the case incidence rate of acute rheumatism in 1921 was 0 9 per 1,000, in 1922 it was 1 1, and in 1923 it was 0 8 Tonsilitis had shown a downward tendency during these years and so had diseases of the teeth and gums

TUBERCULOSIS DISPENSARIES IN NEW YORK

The Year Book for 1922 and 1923 of the Association of Tuberculosis Clinics of Greater New York records that in the year 1908, when the association came into being, the population of the city was 4,469,248, and there were 10,157 deaths due to tuberculosis In 1923 the population had increased to 5 927 617, but the deaths from tuberculosis had dropped to 5 673 Apart from improved conditions of life the work performed by the Association must be largely credited with this satisfactory achievement In the period 1908-23 no fewer than 314 210 patients, including 106,268 children have been advised and treated, 43 455 tuberculous patients were placed in hospitals and sanatoriums, and trained nurses paid 1 193 172 visits The association at present comprises thirty-one dispensaries, with districts covering the entire city area Nineteen of these dispensaries are conducted by the Department of Health, nine by hospitals two is part of a general dispensary service, and one as part of a health centre service This active and close co-operation between municipal departments and private institutions leads to uniformity of procedure, prevents overlapping, and co-ordinates clinical and research work Monthly reports are sent by the dispensaries to the association, which, in its turn, sends back to them quarterly statements of the progress of the campaign throughout the city, including a comparative analysis of the dispensary attendances and studies of the city tuberculosis morbidity and mortality Approximately a third of all cases of this disease reported annually in New York are treated at the dispensaries, where also supervision is arranged for some thirty thousand relatives of these patients

RESEARCH DEFENCE SOCIETY

The ninth annual issue of the *Fight Against Disease*, the publication of the Research Defence Society, contains under the heading "Old stories re-told," notes of certain physiological discoveries made as the result of animal experiments The discovery of the lacteals by Asellius in 1662, Sir Charles Bell's experiments on the nervous system at the beginning of the nineteenth century, and Claude Bernard's discovery of the function of the sympathetic nerve in the rabbit's ear, were important achievements on which, subsequently, valuable researches were based Attention is drawn to the Home Office report published last July, which showed that during the year 14,031 experiments were performed by fifteen investigators in the course of cancer investigations Nearly 39,000 experiments were performed for public authorities by 139 holders of licences, and twenty-eight research workers performed nearly 48 000 experiments for the preparation and testing of antitoxic serums and vaccines, and for the testing and standardizing of drugs The annual subscription for membership of the Research Defence Society is 10s, associate members pay 5s, undergraduates and students of medicine are eligible for membership on subscription of 2s 6d Further information may be obtained from the Secretary, at 11, Chandos Street, Cavendish Square, W 1

At the anniversary meeting of the Royal Society on December 1st it will be proposed to re-elect Sir Charles Sherrington, G B E, M D, as *President*, and Sir David Prain, C M G, M B, as treasurer Among the members proposed to be elected to the Council are Sir Frederick Andrewes, M D, Dr H H Dale, and Professor J B Leathes, M B The Copley Medal has been awarded to Sir E Sharpey-Schafer for his valuable work in physiology and histology, and a Royal Medal to Dr Dale for his researches in pharmacology and physiology

After the ceremony at the Cenotaph in Whitehall, on Tuesday, November 11th, Colonel J W H Houghton, Assistant Director of Medical Services, Eastern Command, laid a wreath on the Royal Army Medical Corps memorial in Westminster Abbey

Dr Walter F Elliot, M C, M P, has been appointed Parliamentary Under Secretary for Health for Scotland in the new Conservative Ministry Dr Elliot held the same office in Mr Baldwin's last Government

THE GENERAL ELECTION

To the list of successful medical candidates at the recent parliamentary general election, published in our issue of last week, the following two names should be added

Dr Arthur Vernon Davies, O B E, was returned as Conservative for the Royton Division of Lancashire with a majority of 2 420 Dr Davies formerly practised at Colne, Lancs, where he was medical officer of health from 1919 to 1924 On retiring he went to live at Woking and is chairman of the Woking Central Conservative and Unionist Association

Dr Henry Cobden Hastam of Cambridge was returned as a Conservative for the Hornchurch Division of Essex with a majority of 11 109 He took the degree of M A, M D, B Ch Camb in 1897 and the D Sc in 1911

Tercentenary of Thomas Sydenham (1624-1689).

SYDENHAM FATHER OF CLINICAL MEDICINE IN BRITAIN *

BY

SIR HUMPHRY ROLLESTON, BT., K.C.B.,
HON. D.SC. OXON., M.D.
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

AMONG the great names of this College those of Thomas Linacre, John Caius, William Harvey, and Thomas Sydenham stand out as the apostles and prototypes of the scholar physicians, of the anatomists, of those who search out and study the secrets of Nature by way of experiment—the physiologist—and of the clinicians, and thus represent important and complementary facets of the ideal physician. Sydenham, the British Hippocrates following in the footsteps of the Father of Medicine not only revived but put into practice the dictum that medicine depends on the observation of not on hypotheses about, disease, and after an interval of twenty centuries he gave a new birth to clinical medicine by concentrating on the study of the patient instead of relying on authority. To books he paid comparatively little heed, it being his nature to think where others read", his attention indeed, was almost confined to the works of Hippocrates, Cicero, Francis Bacon and to *Don Quixote*, the last of which we can picture him recommending with an inscrutable if not somewhat sardonic smile in response to that prolific poetaster Richard Blackmore's inquiry as to what medical books he should read.

After the portrait of Sydenham painted from life by Mary Beale in the possession of the Royal College of Physicians of London.

Coming of an old and distinguished West Country stock the vigour of which is shown by its survival until this present as represented by a direct descendant the Rev. W. B. Vaillant who has spent many years in working at the family pedigree, Thomas Sydenham was baptized at Wynford Eagle in Dorset on September 10th, 1624 but the day of his birth is not known. There has been a good deal of confusion about the date of the birth and baptism of Sydenham, but investigations by the late Dr. J. F. Payne and more recently by Sir Dawson Williams, make it clear that the date of his baptism only is known. The house in which he was born was rebuilt in 1630 and still stands. He was the fifth son and eighth child in a family of ten children, the strongly Puritan atmosphere of which no doubt left its mark on his hereditary character, moulding his character of sturdy independence, modesty, and freedom from self seeking.

In May 1642, when about 18 he went as a Battle Commoner to Magdalen Hall (now Hertford College) then the centre of Puritanism in Royalist Oxford but after a few months the civil war interrupted the course of his life. He was slightly wounded at Weymouth in 1645, and did not return to Oxford until late in 1646. On his way back he visited his brother, Colonel William Sydenham then under the medical care of Dr. Thomas Cove afterwards President of this College (1682), whose kindly interest and advice directed Sydenham to a profession of which he had never previously thought but by which he will never be forgotten.

Returning first to Magdalen Hall he migrated in 1647 to Wadham and on April 14th 1648 was by the Chancellor's (Lord Pembroke) patronage created Bachelor of Medicine, thus reversing the natural order of a degree concluding the course of study. On October 3rd 1648 he was made a Fellow in place of an expelled Royalist and in the following year Bursar, of All Souls, and thus became the friend and a member of the same society as Thomas Millington afterwards President of our College (1696). In passing it may be noted that our founder Thomas Linacre, whose death occurred just 400 years ago on October 20th, 1524, was also a Fellow of All Souls (1484). In 1651 the recrudescence of civil war bore Sydenham away from Oxford for some months as a captain of horse an incident responsible for the phrase "trooper turned physician". Four years later he resigned his Fellowship at All Souls on marrying Mary Gee, and then migrated to London to start practice in King Street in the then aristocratic quarter of Westminster, with its political attraction of the Protector's Court in Whitehall while its swampy and malarial character provided material for his future writings on fevers. That practice did not at once become a gigantic one seems probable from his contesting in his third year of residence, the parliamentary representation of Weymouth and by his acceptance as a consolation for his failure to the office of Comptroller of the Pipe" (1659). But the danger of his becoming absorbed in the duties of a secular was almost at once averted by the restoration of Charles II in May 1660. It was probably about this time (1658) that he visited Montpellier which differed from other French schools in preferring Hippocrates to Galen. The popular teacher there was a Protestant Charles Barbeyrac and the most interesting question arises whether he induced Sydenham's

* Address at a Reception at the Royal College of Physicians of London on November 12th to commemorate the 300th Anniversary of the birth of Thomas Sydenham.

Wynford Eagle Manor Sydenham's birthplace

devotion to Hippocratic simplicity in practice and treatment as Picard and Chauffard patriotically suggest, or whether the two were kindred spirits However this may be, then association confers an additional title to fame on the French physician

As Sydenham's observations on weather and disease in London began in 1661, almost synchronously with the appearance of John Graunt's first *Observations on the Bills of Mortality of the City of London*, he must then have been in practice there again, although it was not until June 25th, 1663, that he obtained from the Royal College of Physicians the licence necessary for legitimate practice, but in those troublous times many others were in the same case until, in 1664, Sir Edward Alston, the energetic President, took the matter up and brought in no less than seventy of them as honorary Fellows That Sydenham was never a Fellow must at first sight excite surprise, and indeed it has been stated by J C Lettsom to have been due to the envy and enmity of the College authorities With his independent and somewhat polemic spirit Sydenham may well in those times of political unrest have had opponents, especially in such a Royalist society as the College, and of this he was fully conscious but a more pleasant and perhaps more solid explanation is that until 1676, when he became an M D —choosing Cambridge, where his eldest son William, also a licentiate at a later date, was then in residence, rather than his own university—Sydenham was not eligible for the Fellowship and at the age of 52 he would naturally be unwilling to submit to an examination and was probably indifferent to any academic advancement Indeed, throughout life he was strikingly devoid of ambition for worldly honours or distinctions he never, so far as is known, applied for any post at the few existing London hospitals or sought for a medical appointment at Court Had he been really anxious to obtain the Fellowship he might have taken the doctor's degree at an earlier period though it is possible that his political associations might have made this a matter of some difficulty That he had many friends in the hierarchy of the College and that his name is mentioned in the most cordial terms in the annals from 1680 onwards is well established

Sydenham's early practice in Westminster included his first case of ascites—Mrs Saltmarsh—described in his *Tractatus de Podagra et Hydrope* (1683), dedicated to Thomas Short, a Fellow of this College, which recall other famous though less successfully treated cases, such as Dame Page, who in sixty seven months was tapped sixty six times and 240 gallons of water taken away "without ever once fearing the operation," and Pye-Smith's patient, Mrs S——, with papilloma of both ovaries, who was tapped 299 times in nine years "without once complaining of her lot" During the plague of 1665 Sydenham with his wife and young family left London—a course of action which has aroused some adverse comment, but at this distance of time a just judgement of circumstances is not so easy as offhand condemnation His practice eventually became extensive, but as he was a Puritan amongst Royalists it was somewhat slow in developing, and he may have been handicapped by his outspoken opinions, candour in expression of his doubts, independence in ploughing a lonely furrow, and by his new methods—such as the cooling treatment in small pox and the use of quinine, or "Jesuits' bark," against which medical prejudice persisted many years after his death His fondness for prescribing opium ("laudanum Sydenham's") earned him the title of "Opiophilos," and he relied much on the *vis medicatrix Naturae* Dr John Brown in *Horae Subsecivae* called him "the Prince of Practical Physicians," and rightly, if alliteratively, so, for his sole ambition was to examine his patients thoroughly and do the best possible for them

Thomas Dover, buccaneer and 'the quicksilver Doctor' whom he treated for small-pox, and Hans Sloane, the future President of the Royal Society and of this College, who whimsically advised to drown himself in Pomfret's pond in St James's Park rather than go on a botanical expedition to Jamaica were for a time his resident pupils

His face has been described as puritanical yet benign "the fine brow, melancholy eye, and sensitive mouth remain a nature stoical rather than harsh, and rather that of a Puritan under protest" (J H Garrison)

The gout claimed Sydenham before, in Sir Thomas Browne's phrase, his 'pulse beat thirty years,' a stone attacked him at the age said to be fatal to genius, or 37 Erasmus's epigram, I have renal colic, you gout we have married sisters," makes Sydenham unfortunate The gained on him, sadly hampering

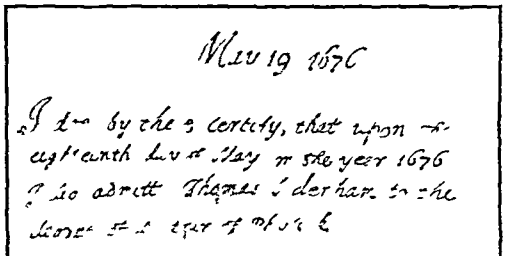
practice and literary output, and eventually he died on December 29th, 1689, in his house in Pall Mall, where he had lived since 1667, and was buried in St James's Church, Piccadilly, where a tablet, erected in 1810 by the College of Physicians, in the south wall aisle eloquently describes him as 'Medicus in omne aevum nobilis."

To recall his works by name would be as unnecessary as it would be lengthy, for they are immortal, especially those dealing with fevers, the distinction for the first time of scarlet fever from measles and of rheumatism from gout, and the classical descriptions of chorea and of hysteria. Scholarly criticism has been much concerned about the question whether Sydenham originally wrote in English or in Latin, the conclusion that appears to have most in its favour is that he composed in the language he spoke and that Dr John Mapletoft and Gilbert Havers, a scholar, did his text into Latin. But whatever medium he used he painted from Nature, and, with the artistic instinct of a great clinician emphasized the essential and kept the immaterial in due proportion.

In his attitude of "back to Hippocrates," whom he called 'the divine old man," and the principle of observation rather than the precepts of authority Sydenham insisted on the importance of the accurate description of the natural history of diseases, the constant and essential symptoms being distinguished from the accidental; he also advocated their separation into species, as in the classification of animals and plants there being a common resemblance in their seasonal variations. Thus regarding diseases as specific, he urged that specific remedies should be sought for them. Sydenham has accordingly been regarded as the founder of scientific nosology. Further, he urged that a definite system of treatment should be established on rational grounds instead of on polypharmacy. As J. F. Payne, in comparing these two Masters of Medicine, who, as far as we know, never met, writes, Sydenham was the Master of Practice, while his contemporary William Harvey was the Master of Science.

The importance of Sydenham's practical outlook on medicine can hardly be over-emphasized, but this is not his only claim on our remembrance, for in his attempts to obtain a cure for epidemic fevers he made observations on their incidence and variations which led to his famous hypothesis of epidemic constitutions"—a somewhat mysterious conception of a more elaborate character than those of Hippocrates and Ballonius (Guillaume Baillou) in 1574. His view of acute especially epidemic diseases was to the effect that they were modified by the additional factor of a constitution or influence derived not only from the atmospheric and weather conditions, as Hippocrates believed but from telluric and other sources; thus upon a specific disease in the modern bacteriological sense, are superimposed features due to a common factor, which however varies in the course of years and gives rise to what he termed "stationary fevers." Thus in the years 1661-64 "the epidemic constitution" was malarial; in 1665-66 plague like; and in 1666-69 like small-pox. That accomplished scholar physician, the late Joseph Frank Payne—sometime our Harveian Librarian—in his masterly life of Sydenham expressed the hope that his sketch should induce some readers to study for themselves Sydenham's own works." Since then several Fellows of the College—Sir William Hamer, Dr F. G. Crookshank and Dr Major Greenwood—have devoted much thoughtful consideration to the epidemic constitutions and Sydenham has been rightly described by Dr E. W. Goodall as "the founder of the modern science of epidemiology." By a kind of prophetic sense he seems to have foreseen that bacteriology might appear and be held to explain the whole question of the incidence of acute disease, and at any rate he provided reservations to such a simple and exclusive conception.

Thus the three hundredth anniversary of the birth of the Father of Clinical Medicine in Britain and the Prince of Practical Physicians of the Founder of the modern science of epidemiology and of the originator of scientific nosology—"the incomparable Sydenham"—should be kept in grateful and proud remembrance in his Country and College.



THOMAS SYDENHAM: HIS WORK AND CHARACTER

BY

ARNOLD CHAPLIN, M.D., F.R.C.P.,

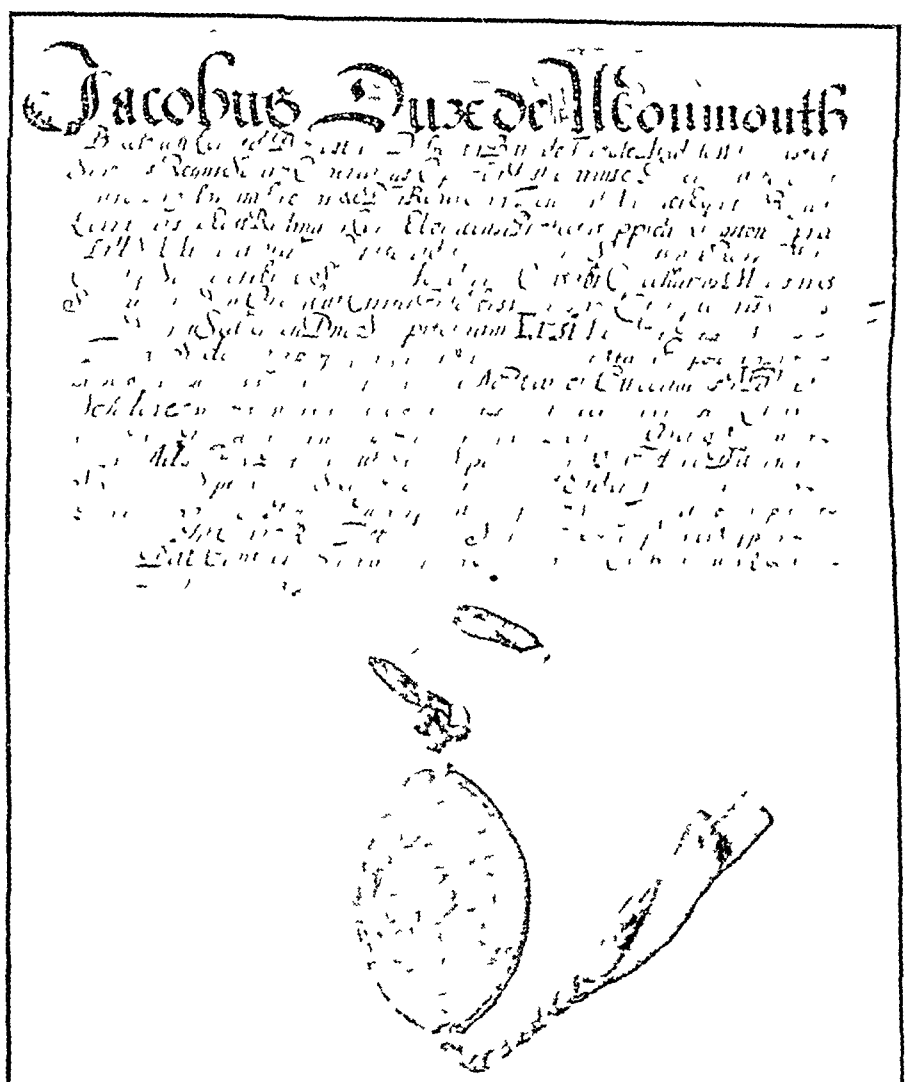
HARVEIAN LIBRARIAN

In the annals of medicine in this country three men may be found who by universal consent are honoured above all others. They are William Harvey, John Hunter, and Thomas Sydenham. Special measures have been taken to prevent the glory belonging to Harvey and Hunter from ever becoming dim, for a wise provision has established societies and annual orations designed to perpetuate in the minds of medical men the memory of those great pioneers in medical and surgical science. But Thomas Sydenham, although his labours have left an effect upon medicine scarcely less than the work of the other two, has never been honoured by an annual oration for the purpose of keeping alive the memory of his great achievements. Indeed, apart from the society for medical publications bearing his name, the issue from time to time of his collected writings, and attempts sometimes inadequate to portray his life and activities, but little has been done to fix the public gaze upon the monumental work of this

May 19 1676

I do by these certify, that upon the eighteenth Day of May in the year 1676 I did admit Thomas Sydenham to the degree of the right of Physick

Isaac Barrow Regius Professor Cantabrigiae



Isaac Barrow's certificate showing the date of Sydenham's degree in the possession of the Royal College of Physicians.

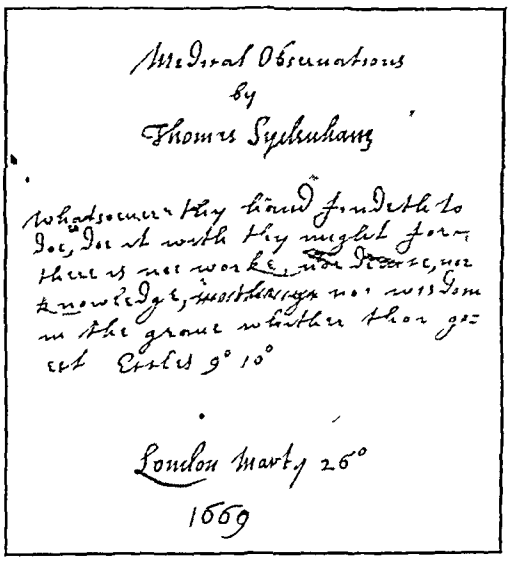
most 'English" of English physicians—this rugged genius who unaided laid the sure foundations of clinical medicine. Now in this year 1924, three hundred years after his birth a tardy recognition of his merit is being laid at his shrine. French medicine, ever ready to award a scientific crown wherever it is deserved irrespective of nationality, has already paid its tribute to one of England's greatest medical sons. And now a great journal voicing the thoughts of thousands of British medical practitioners in the tongue that Sydenham spake and in the land that bred him is placing on record its deep appreciation of the work he accomplished. At the same time the Royal College of Physicians of which body Sydenham was a distinguished member has held a special evening session and through the mouth of its President Sir Humphry Rolleston himself a great clinical physician has paid the debt it owes for the glory of having the name of Sydenham on its roll. This action of the College of Physicians is peculiarly fitting for it is well known that for reasons somewhat obscure to us at the present time Sydenham never applied for the Fellowship of the College nor was that honour ever offered him although for the last thirteen years of his life he was in every way eligible. But this gathering of the Fellows of the College in the twentieth century for the purpose of doing honour to Sydenham's name will surely be regarded as an adequate act of penance for its omission three centuries ago. Nor must we feel aggrieved that medicine in a foreign land has paid its tribute earlier to our Sydenham in this year the tercentenary of his birth for his influence upon medicine was so great that it left its mark in whatsoever land it was practised. It knew no national boundaries. That vigorous influence wrought for all time

and for all countries, and we do not, therefore, grudge our colleagues their first-offerings of homage to the name of Thomas Sydenham.

It is not the purpose of this article to write a biography of Sydenham, for that has been done with great ability and discrimination by the late Dr Payne, but rather to consider his character, his mental environment, and the results for us to-day of his work. Some biographical details will, however, be necessary in order to appreciate the true position occupied by Sydenham as a great medical reformer.

Thomas Sydenham was born in 1624, at the Manor House of Wynford Eagle, in the county of Dorset. The exact date of his birth is not recorded, and it can only be stated that he was baptized on September 10th of that year. He came from an old Somersetshire family dating back to the time of King John, which multiplied exceedingly for no less than eight branches were founded in that county. One of the branches was settled at Aller, and a cadet of this branch acquired, in the middle of the sixteenth century, the Manor of Wynford Eagle from Zouch, Lord of Harringworth. The Manor of Wynford Eagle once formed part of the great Honor of the Eagle, granted by the Conqueror to one of his companions, Gilbert, whose chief castle was at Pevensey in Sussex. Gilbert came from Aigle (Aquilla) in Normandy, and the Honor no doubt derived its name from that source.

Diploma granted to Sydenham on taking the degree of M.D. at Cambridge. From the document in the possession of the Royal College of Physicians.



The Manor House of Wynford Eagle stands by itself at the bottom of a shallow valley in the downs of Dorsetshire, with a clear chalk stream flowing swiftly in a mossoned channel at the end of the garden. It is a well kept substantial building of grey stone stained with lichen. Its chimneys are of red brick in the picturesque style of the early seventeenth century. It has the large casemented windows of the period and the garden walls and parts of the side walls of the house are composed of the characteristic local chipped flints in panels. In the centre of the front of the house, which faces west, is a projecting porch with a room over it. On its gable is placed an eagle in stone and under it the date 1630. Another eagle of older date and much battered, taken down probably when the house was repaired, still stands at the top of some steps in the yard. In 1630 Thomas Sydenham was 6 years old and save for some inconspicuous farm buildings the place must be now very much as it was in his boyhood. It looks to-day a very home of ancient peace though in Sydenham's time it gave shelter to a family of valiant sons who issued forth to the stern business of fighting for the Puritans against the Royalists.

Long before the actual struggle began, the Sydenham family had become deeply committed to the Puritan cause, and Thomas Sydenham was therefore brought up under strict Puritan influences. The adherence of the family to this cause was no mere formal acceptance of its tenets, for, when the civil war broke out, the father and his two sons bore arms for the sake of their consciences on the side of the Puritans, and two of them lost their lives in battle. Thomas Sydenham had only been at Oxford for a few months when the summons came. He at once threw aside the gown for the sword, and took his place beside his valiant brothers, ready to risk all for the honour of his belief.

So far as is known, only one other member of the College of Physicians, Dr Martin Llewellyn, actually bore arms in the civil war. At the conclusion of the first civil war Sydenham again returned to Oxford in 1646, and, acting on the advice of Dr Thomas Coxe, a physician in the Parliamentary army, devoted himself to the study of medicine. In 1648, being then a Fellow Commoner of Wadham College, he took the degree of M.B. on the recommendation of the Chancellor, the Earl of Pembroke, and a few months later was elected a Fellow of All Souls. In 1650 he again obeyed the call to serve in the army, and was employed in Scotland and elsewhere, but there is no evidence that he was present at the battle of Worcester, as has been asserted. After this Sydenham remained at Oxford until 1656, when he removed to London and settled himself in practice in Westminster. During the year 1659 he paid a visit to Montpellier, but with the exception of that brief period of study, lasting less than a year, Sydenham's career was unconnected with any of the medical schools abroad. It was not until 1663, although he had already been in practice in London for some years, that he obtained the Licence of the College of Physicians to practise, and the Licence of the College of Physicians to practise, and the 1676 he took the M.D. degree at Cambridge. When the great plague devastated London, Sydenham followed the example of nearly all the London physicians, and absented himself with his family from Westminster. This action must always be a matter for regret, for, had he remained in London, we might have possessed an almost perfect picture of that great epidemic. But during his absence from London he was not idle, for he began to plan to record the results of his own observations concerning disease, and especially fevers. Since the year 1661 he had been engaged in taking these notes, and in 1666 he had

to the world his first work, *Methodus Curandi Febres*, in which the treatment of disease was approached from an entirely new standpoint

This book of Sydenham may be regarded as epoch making, for it was the first treatise founded on the personal observation of the physician at the bedside when attending cases. Before his time it was the almost universal practice of physicians when writing of disease to appeal entirely to the ancient authorities and to neglect what their own senses had taught them. Vesalius and Harvey had already definitely broken with this tradition in the sciences of anatomy and physiology and it was reserved for Sydenham to take the same bold step in medicine. With a knowledge, scant it may be, of the principles of medicine, he literally rejected all that had been written concerning the practice and relied absolutely on his own unrivalled powers of observation. With two important exceptions, Sydenham had a profound contempt for the knowledge of medicine to be found in books both ancient and modern and to the last refused to be influenced by their authority. The teachings of anatomy and physiology which had received such an impetus from the work of Vesalius and Harvey made no impression upon him and he dismissed them from his system almost with contemptuous disdain. He was wedded to the *belief that personal observation*, and personal observation alone, could unravel the mysteries of disease. Chemistry, physiology, and anatomy might be amusing and perhaps instructive as sciences, but he thought that they could lend no aid to the purpose he had in view. The two important exceptions mentioned above, to which he accorded his approval, were the Hippocratic writings and the philosophy of Bacon. For the former he had unbounded respect, because he was convinced that the teaching of the Father of Medicine was based on clinical observation, while from the latter he took the main principles of Bacon's system and applied it to the study of disease. The essence, therefore, of Sydenham's great innovation is to be found in the fact that he was the first to teach the great truth that disease could only be understood by watching its progress at the bedside of the patient, or, in other words, by studying Nature herself. The fine apophthegm of Bacon, which being translated reads "We must not imagine or think, but find out what Nature does or produces," most aptly expresses the essentials of Sydenham's work.

Title page of Medical Observations in Sydenham's handwriting. From the manuscript in the possession of the Royal College of Physicians.

We must not be astonished to find that Sydenham's method was often responsible for faulty ideas concerning disease. That was inevitable for the method was far from perfect, and much progress in the knowledge of disease had to take place before it could yield definite results. Nevertheless from the time that Sydenham launched upon the world his clinical method that branch of medicine has continued to advance and has been seen in its highest excellence in the hands of Heberden, and Boerhaave in the eighteenth century and of Bright, Addison, Watson and Trousseau in the nineteenth century.

Sydenham's book on fevers was considerably expanded in successive editions until it embraced nearly the whole of his observations concerning disease as he saw it and a particular merit of his writings is the clear and faithful descriptions of the clinical features of various ailments. Indeed, as Dr Payne observed, his descriptions of many diseases are "so admirable that they have never been surpassed nor are likely to be." This was particularly the case in his dissertation on gout, where his account of the symptoms of that complaint is so vivid and true that writers have been content to follow it without alteration. While advocating his new clinical method in his book on fevers Sydenham laid the foundation of the study of epidemiology and may therefore be regarded as the father of that branch of medicine in this country.

In estimating the cast of mind of Sydenham regard must be paid to his upbringing. He was nurtured in a strict Puritan household, and throughout his work the Puritan influence is abundantly evident. He had risked his life on the field of battle for the cause he believed to be right and he was just as ready to risk unpopularity and criticism in promulgating views concerning the practice of medicine which were new and therefore suspect. He often complained, somewhat bitterly, of the adverse criticism of his contemporaries but like a true Puritan it could not turn him a hair's breadth from the course he had planned. In medicine his was a voice crying in the wilderness, and again as a Puritan he probably accepted the position with some satisfaction. He drove home the great truth that the solution of the problem of disease, its manifestations, and its cure must be sought at the bedside by means of observation and inquiry, and not by an appeal to theory and authority sanctified by time. Before the end of his life he saw that his work had not been in vain but it was not until the eighteenth century dawned that the full effect of Sydenham's teaching was felt. In that century it may be truly said that the whole of practical medicine was dominated by the system of Thomas Sydenham. At the present day the influence of his great work is not so apparent. Nevertheless in this the three hundredth anniversary of his birth our homage is no less sincere for in him we recognize the master who made straight the road up which countless physicians have toiled to realms of more perfect medical knowledge.

Very little has been left by Sydenham in the shape of letters and manuscript. The Royal College of Physicians possesses one most important manuscript entitled *Medical Observations by Thomas Sydenham*, a folio volume containing his observation on various diseases the first page of which is reproduced above. It is not a manuscript of any complete work of Sydenham but merely his notes probably written down from time to time and it is doubtful if the whole of it is in the handwriting of Sydenham. The College also has in its possession the signature of Sydenham

Sydenham's signature. From the subscription book of the Royal College of Physicians.

on admission as a licentiate in the subscription book of the Fellows, and this has also been reproduced. Two interesting exhibits referring to Sydenham have been reproduced. One is the certificate given by Isaac Barrow in which he was Vice Chancellor at Cambridge and in his hand certifying that Sydenham had taken his degree of M.D. The other is the diploma given to him by the University on taking his degree.

Several portraits of Sydenham are in existence and three belong to the College. The most important is the portrait painted from life by Mary Beale, and this is reproduced

at page 917 Another in the possession of the College is attributed to Lely or Closterman, and fine portraits are in the possession of the Wellcome History Museum and Sir Thomas Barlow The Mary Beale portrait, and that attributed to Closterman or Lely, have been engraved in line and mezzotint by Houbraken, Seiller, and McArdell

SYDENHAM REFORMER OF ENGLISH MEDICINE

To celebrate the tercentenary of the birth of Sydenham Sir George Newman has written a biographical essay[1] which is among his happiest efforts It is not long, it is comprehensive, and it is, almost needless to say, intensely sympathetic, for Sir George Newman, like Dr Arnold Chaplin, comes of Puritan stock Though Puritanism was at its beginning a religious movement, it was in its essence a habit of mind, which those possessed by it applied to all institutions and all departments of mental activity Thus Sydenham, who held strong religious and political views as to individual liberty, and fought for them in the field, applied the same principles and showed the same love of independence when he came to study and practise medicine

Sir George Newman's essay contains five chapters or sections dealing successively with Sydenham at Oxford, and in London, with Sydenham as a physician, with his little books, and with Sydenham the man Rather more is said in the essay than in the two articles published above about the Oxford period, with a few months interruption, when Sydenham fought again under Cromwell, it lasted for fully eight years That he took an active part in the life of the University is shown by the fact that he was bursar as well as Fellow of All Souls College, he must have known every one he wished to know, and certainly numbered among his friends many men already distinguished or afterwards to become so Whether he became acquainted with John Locke at Oxford may be doubted, but they afterwards grew to be fast friends, and Locke's resolve to begin the study of the principles of philosophy by setting down "on a piece of paper" the limits of human understanding must have been much to Sydenham's taste

Of the Westminster to which he took his bride in 1655 we have a graphic sketch There were the Abbey and Westminster Hall, and Whitehall Palace, some houses of courtiers and official persons, and hovels of the poor, with the swamps and marshes of the unconfined Thames around

> 'The Palace consisted of a vast congeries of buildings and pleasure grounds, covering almost the whole of what we call Whitehall through which passed the public highway King Street between the glorious Holbein Gate (which stood until 1759) and the High Gate built by Richard II It was a narrow street with a network of smaller streets and courts on either side at its southern end Here Sydenham lived The houses rose three or four storeys gabled all, with projecting fronts the timbers painted or gilt some of them bearing escutcheons or brightly blazoned arms or carven beams or signs There were taverns and much coming and going wagons, packhorses, pedestrians, and the motley crowd which frequent camps and courts Down it passed the pageantry of funerals, coronations and State shows Lord Howard of Effingham set out from King Street to fight the Spanish Armada Charles came down it to his trial in Westminster Hall Cromwell lived in it, and Colonel Sydenham and many of the parliamentary leaders and soldiers

There and afterwards in Pall Mall, Sydenham lived until his death, with apparently only two long absences, one in 1659, possibly, we may suggest, connected with the approaching Restoration, when he went to Montpellier to study under Barbeyrac, the other in 1665 when the plague was in London, when he retired a few miles "Had he remained," Sir George Newman drily remarks, "medical literature might have been enriched by an adequate description of the plague"

Of Sydenham's disregard of the contemporaneous or almost contemporaneous work of others, Sir George Newman has no explanation *It seems very strange,* he writes Perhaps it was temperamental, perhaps a studied effort to exclude the influence of others upon his own mind Yet it is rightly claimed for him that 'the principles of direct clinical study, or the non-reliance on tradition and the return to Nature, of the scientific method of observation and induction, laid down by Sydenham as the foundation of sound medical practice, will endure for ever" It must be remembered that Sydenham's practice was very largely concerned with fevers, and he set himself to define in orderly and systematic scheme of clinical study to consist of three parts (1) an exact description of the disease before him, (2) a method of remedy, and (3), where he could discover them, the use of specific forms of treatment" Sir George Newman looks on Sydenham as having laid the foundation of modern epidemiology he saw that certain fevers had an epidemic character which bred true, but there were, he thought, variations, the same disease manifesting itself with dissimilar aspects as to origin, formation, and decline While he began 'to feel out after the idea of contagion, though not very much," yet he believed that "both typical and atypical fevers prevailed at certain times, dependent, he thought, upon meteorological or atmospheric conditions, or other external influences" Associated with these views was his theory of epidemic constitution, which he seems to have derived from Hippocrates We find in the essay no very definite opinion on its worth The controversies to which it has given rise have perhaps rather tended to obscure the great merit of Sydenham, which lies in his insistence on accurate bedside observation *coupled with a system of rational therapeutics* founded on careful record of the action of remedies administered with the intention of assisting Nature's own efforts to overcome the disease

Scotland.

THE Branch Council for Scotland has certified to the returning officer that Sir Norman Walker, M.D., has been duly elected a direct representative for Scotland upon the General Medical Council in accordance with the regulations made by the Privy Council

HOUSING IN GLASGOW

The provision of dwelling-houses is a serious problem for Britain as a whole, and it seems to be admitted that the general standard is lower in Scotland than in England Within Scotland it is difficult to believe that any locality can be worse off than Glasgow Whether private enterprise could have continued to meet the needs of the city, as it did in a fashion until within the last score of years, we do not profess to say, but clearly the no-rent developments in Clydebank are sufficient to deter the cautious Scot from risking his money in any such speculation, and so the problem is transferred to the local and central authorities The valuable report for 1923 of Dr Chalmers, the medical officer of health, shows how deplorable the whole position is, notwithstanding building schemes at present being carried out A margin of 325 unoccupied houses in 1923 is wholly inadequate, even if all of them were suitable in size and otherwise for the families requiring them In the past five years the average annual addition to the number of new houses has been slightly more than 1,200 But the average by which the births exceeded the deaths in the past four years has been more than 10,000 The Registrar-General for England assumes two persons per room as a permissible standard, but a room in Scotland being commonly larger than in England, Dr Chalmers takes three persons per room as his measure of existing needs Following the 1921 census report for Scotland, and leaving aside 24,653 houses of one apartment occupied by not more than three persons each, 86,425 houses of two apartments occupied by not more than six persons each, and so on for larger houses, Dr Chalmers says there remain 14,131 one-roomed houses occupied by from four to six persons each, 1,643 occupied by seven to nine persons each, and 62 houses of one apartment in which there are between ten and twelve persons each Of two-apartment houses there are 19,590, occupied by from seven to nine persons each, 2,832 by from ten to twelve persons, and 117 by more than twelve occupants If the rate or increase of house accommodation in the decade 1891-1901 persisted now, the annual provision would have

been 3,804 new houses instead of 1,200 In fact, he urges, 'instead of the shortage becoming reduced, it is increasing" He then proceeds to show that the average size of the apartments under the Glasgow housing scheme is considerably less than under the building regulations, as regards both floor area and cubic space, and he remarks that "the size of the smaller bedrooms cannot be regarded without some apprehension of its effect on our conception of a healthy house" He follows up the whole statement by giving statistics to show that pulmonary tuberculosis prevails broadly speaking, in a kind of inverse ratio to the number of apartments in the houses The percentage of population in one roomed houses is 12 9, but they have 17 96 of the pulmonary tuberculosis, while the corresponding figures for two roomed houses (the commonest size in Glasgow) are 49 5 and 49 93 per cent Beyond that size of house the position is reversed Three roomed houses have 21 0 per cent of the population, but only 15 74 per cent of the pulmonary tuberculosis while houses of four apartments and upwards have 16 0 per cent of the population and only 8 41 of the pulmonary tuberculosis The rest of the cases are in institutions *Corrections for age and sex* distribution make some change in these percentages, but no essential alteration in the lesson they teach

Successful Glasgow Medical Charity

Last week a three days' bazaar was held in St Andrew's Hall, Glasgow with the object of raising a sum of £70 000 in aid of the Royal Samaritan Hospital for Women in Glasgow The promoters were gratified by being able to announce that the total sum realized on behalf of the hospital was £77 786, which with other sums still to come in, would eventually amount to £80,000 The bazaar was opened on the three successive days by the Duchess of Brandon and Hamilton, Sir John Stirling Maxwell, and Lady Blythswood

Longmore Hospital for Incurables

The annual meeting of the Royal Edinburgh Hospital for Incurables was held on November 7th, Sir Henry Cook, *Chairman of the Board of Managers*, in the chair Sir Leslie Mackenzie of the Scottish Board of Health, moved the adoption of the annual report, which was seconded by Sir Herbert Stiles The report pointed out that the hospital had now been in existence for fifty years, having been founded as the result of a public meeting held on December 1st 1874 In consequence of the original effort, a house in Salisbury Place, Edinburgh, was purchased and fitted with twenty two beds At the present date there are two hospitals—one on the original site, and one at Liberton, some distance outside Edinburgh, the two together providing accommodation for over two hundred patients The report drew attention to the benefits coming to sufferers from such a disease as cancer from the ministrations of the skilled nurse and daily medical supervision, benefits wholly beyond the resources of the average small household The same might be said of patients suffering from other forms of incurable disease, such as heart disease, tuberculosis, affections of the spine, etc, but cancer was especially considered because such cases were often very urgent and short-lived During the fifty years the managers had made every effort to extend the benefits of the hospitals, but practically all the time they had had to face a shortage of income During the first twenty years of the hospitals' existence the total deficiency was under £2 000 but for the whole period of fifty years the total sum drawn from capital to meet deficiencies on annual income had amounted to over £93,000 In pre war years there had been a considerable margin between the legacies received and the amount of the deficit for each year so that after making up the deficit the managers had been able to put aside fairly large sums for extensions and similar purposes Unfortunately, the same could not be said with regard to post-war years, and thus the possibility of future extensions would be seriously curtailed The total number of patients treated during the past year had been 345, and the average cost per occupied bed for the year taking both hospitals into consideration, was approximately £82 10s 1d which was a decrease of 1s on the cost for the preceding year, this cost compared very favourably with that of other institutions *The report* particularly noted that the two Longmore Hospital receives cases from every part of Scotland, and occasionally from England they are intended for the treatment of those for whom the general hospitals had done all in their power, but who are still in need of hospital treatment, and for this reason a preference is always given to cases of cancer advanced heart disease, tuberculous disease, and some of the more devastating forms of nervous disease But the aged and infirm, who only need general attention and assistance are not cases suitable for treatment in these hospitals The medical report stated that 73 of the patients were suffering from cancer 58 from advanced tuberculosis, 30 from disease of the circulation, and 99 from diseases of the brain and spinal cord These formed over two-thirds of the total admissions

Edinburgh Royal Infirmary

At the fortnightly meeting of the Board of Managers of Edinburgh Royal Infirmary last week it was reported that the receipts since the previous meeting had amounted to £6,896 It was reported further that 1,501 patients had been under treatment in the wards during the period, and that *the number of cases awaiting admission to the* institution was 1,813 at November 1st

Ireland.

THE Branch Council for Ireland has certified to the returning officer that Dr Leonard Kidd has been duly elected a direct representative for Ireland upon the General Medical Council in accordance with the regulations made by the Privy Council

Irish Medical Committee

A *special meeting of the Irish Medical Committee* was held recently in the Royal College of Surgeons Dublin, with Dr Joseph Power in the chair The chief business the *Committee* considered was a draft statement of evidence prepared by the Executive Subcommittee to be submitted to the Committee of Inquiry appointed by the Irish Free State Government to report in connexion with the Insurance Act in its application to the Free State and also the extent of the reforms that would be necessary in the existing medical services to bring them more up to date and more efficient generally The report of the Executive Committee was considered at length and, with some alterations, was adopted The following deputation was appointed, and waited on the Committee of Inquiry on November 7th Dr J Power, Senator W O'Sullivan, M D, Dr J M Day, Dr P Magner, Dr J P Shanley Dr J Counihan, Dr Hennessy (Medical Secretary) and Mr C H Gick (Secretary) The deputation amongst other matters, urged upon the Committee of Inquiry the acceptance of the following recommendations

1 The co-ordination of the system of central control of the medical and public health services in Ireland by the establishment of a Ministry of Health for Ireland (Free State)

2 The formation within the Ministry of a Health Council composed of representatives of public and professional interests to which will be entrusted the general direction of policy in regard to the administration of the medical and health services in Ireland

3 The establishment of an Irish Medical Service appointed by competitive examination of an entirely practical nature and paid by the Ministry from which will be provided the medical and veterinary officers of health the medical and surgical staffs of the various public hospitals sanatoriums asylums etc as well as the medical officers engaged in the treatment of the insane and of poor persons

4 The transformation and development of the present dispensary medical system freed from association with Poor Law administration and under which certain classes of persons will be entitled to receive medical hospital and special treatment

5 The modification of the existing scheme of Salaries and Conditions for medical and public health service and the substitution therefor

of a scheme under which the net expenditure of the local health boards, after deducting receipts from insurance etc sources, will be defrayed in equal proportions by the rates and the State

6 The classes entitled to medical treatment both general and hospital, under the new service would be (1) insured persons, (2) the poor and destitute, and (3) a class of persons who though not insured, correspond socially or industrially to the insured, and who might be included as voluntary contributors The income limitation of (1) and (3) and the terms and conditions of their inclusion should be a matter for arrangement between the Ministry and the representatives of the profession

7 The proposal to provide medical benefit for dependants presents considerable difficulties, particularly in urban areas, where it would interfere very largely with the work at present done by private practitioners The Irish Public Health Council recognized this difficulty and postponed any proposals for dealing with dependants The Irish Medical Committee cannot advise that medical benefits should be given to dependants It must, moreover, be borne in mind that the provision of medical benefit for dependants would treble or quadruple the cost of providing medical benefit for insured persons alone

8 In connexion with public health the deputation recommended (1) the appointment of whole time county medical officers of health (2) the medical inspection of school children, (3) mother and child welfare schemes

The Irish Medical Committee passed resolutions protesting against exclusion of any existing medical officials from the advantages (for superannuation purposes) of Section 8 of the Local Government (Ireland) Act of 1919, and urging that all future medical officials should have compulsory pension rights

On the motion of the chairman a very warm vote of thanks was passed to Dr R J Rowlette, F R C P I, for his long and invaluable services to the Irish medical profession, especially as a member of the Irish Public Health Council and the Committee of Inquiry now sitting in connexion with the Insurance Act and the medical services in the Free State

Ulster Medical Society

The first meeting of the winter session of the Ulster Medical Society was held in the Medical Institute, Belfast, on the evening of November 6th Professor Symmers, the retiring president, introduced his successor, Dr Singleton Darling (Lurgan) in felicitous terms Dr Darling proposed, and Dr McKisack seconded, a warm vote of thanks to Professor Symmers for his conduct in the chair, for all his efforts on behalf of the society, and for his hospitality This was passed by acclamation and conveyed to Professor Symmers Before taking up the subject of his address, "Some Observations on Public Health and Poor Law Medical Service," Dr Darling referred in feeling terms to the five deaths that had taken place in the last year Sir Wilton Browne, Professor Symington and Dr J McCan, all past-presidents of the society, and Dr Agnew, of Lurgan, and Dr J L Rentoul, of Belfast, both vice-presidents He returned his grateful thanks for the honour of being president Dr John Campbell proposed, and Dr R J Johnstone M P, seconded a hearty vote of thanks for the address this was supported by Colonel Dawson, Chief Medical Officer to the Government Dr William Burns, and Dr Patton (Lurgan), and passed with acclamation

County Mayo Doctors' Salaries

At a meeting of the County Mayo Board of Health a letter was read from the Ministry of Local Government relative to a graded scale of salaries for dispensary medical officers existing prior to the amalgamation scheme The Minister desired to point out that as far back as 1920 Westport Union recognized the inadequacy of the salaries of medical officers and submitted a scale rising to £250 per annum This received the sanction of the old Local Government Board The Minister considered that the time had now come when a settlement of the claims should be arrived at, and requested the Board to take the matter into consideration and formulate a reasonable scale and submit it for the approval of the Ministry The Board, one member dissenting, refused to formulate a scale of salaries as suggested in the letter of the Minister of Local Government and Public Health

England and Wales.

The voting papers for the election of direct representatives for England and Wales upon the General Medical Council were posted on November 12th They must be returned to the Registrar not later than November 20th

Tuberculosis in Lancashire

The annual report for 1923 of the central tuberculosis officer for Lancashire (Dr G Lissant Cox) has just been published The population dealt with under the county scheme was estimated at the end of the year to be 1,772,658, and the number of cases of non-pulmonary tuberculosis under supervision was reported as 5·65 per 1,000 of the population The death rate for the year from pulmonary tuberculosis was 0·70 per 1,000—the lowest ever recorded in the administrative county The death rate from non-pulmonary tuberculosis was, however, 0·23 per 1,000, fractionally above that of the previous year Sanatorium and hospital accommodation was slightly increased during the year, the number of beds under occupation at the end of each year rising from 678 in 1922 to 750 in 1923 The care committee organization of the county has been increased, there now being 17 voluntary care committees dealing with a population of 780,173, but leaving out a population of nearly one million An amended scheme is therefore being brought into force to extend this valuable work to cover the whole of the administrative county During the present financial year the county grant for care work is to be increased, and, where these committees do not exist, fixed sums have been allotted for the first six months to be disbursed on the recommendation of the consulting tuberculosis officer in the relief of necessitous patients In this way help can be given in the purchase of clothing by patients going to a sanatorium or hospital, and food and clothes provided for patients under treatment at home The proportion of consumptive patients sleeping in the same bed with other persons has decreased from 17·1 per cent in 1921 to 10·1 per cent in 1923, as a result of the council lending bedsteads and mattresses to patients unable to provide for themselves Dr Cox draws attention to the unsatisfactory feature that only a quarter of the 1,238 adult patients applying for treatment for the first time in 1923 were in the early stage of pulmonary tuberculosis, and he urges the importance of educating the public further in this respect Improvement is reported in the matter of notification, less than 7 per cent of the deaths from this disease in 1923 occurred without previous notification, as compared with 18 per cent in 1918 In only 7 per cent of the cases of death in which notification had not taken place was there no reasonable excuse for the omission

Continued improvement is recorded in the matter of co-operation with sanitary authorities, medical practitioners, and health officials In the year under review 76·6 per cent of the new cases, excluding contacts, were referred to the tuberculosis officers by practitioners, poor law authorities, school medical officers, or other health officials Tuberculosis officers occasionally visit Poor Law infirmaries for consultation purposes, and in one dispensary area the consultant tuberculosis officer pays such a visit at regular monthly intervals Research work of different kinds is proceeding, and the county tuberculosis committee has decided to set apart a sum of money specifically for research by the tuberculosis staff, so as to prevent the cost of this falling as an extra charge on particular institutions Whereas during the years 1881 to 1910 the prevailing type of tuberculosis in Lancashire was the "middle age" type affecting persons between 35 and 55 years, Dr Cox's examination of the returns for 1923 showed that the mortality was now heaviest among the "young adult" group, aged 20 to 25 The cost of the county scheme for tuberculosis, allowing for Government grants, has required a county rate of a little over 1½d in the £ for the current financial year For dispensary purposes the county is divided into five large areas and two sub areas, five of these and eighteen branch dispensaries being in active op-

tion The complete county scheme requires three more branch dispensaries During the year 1 535 contacts were examined, of whom 119 were diagnosed as cases of definite tuberculosis, representing 77 5 per 1 000 contacts examined, a much higher figure than any random sampling of the ordinary population would give The x ray work increased considerably as compared with previous years

Dr Lissant Cox has come to a definite conclusion as regards the value of sanatorium treatment A statistical analysis is given of the after-histories of 2 228 patients who received sanatorium treatment and of 1,640 patients who received treatment at home or in institutions other than sanatoriums Of 927 sanatorium patients, and 700 non-sanatorium patients, in the early and intermediate stages of disease, 17 per cent of the sanatorium patients had died as compared with 45 3 per cent of the non-sanatorium patients at the end of 1923 Similarly, of 1,301 sanatorium patients and 940 non sanatorium patients in later stages, 69 2 per cent of sanatorium patients as compared with 87 4 per cent of non sanatorium patients, had died by the end of 1923 He adds that the educational value of sanatorium treatment is also a point of very great importance

Maudsley Hospital Clinics

The Maudsley Hospital offers facilities for the clinical study of all types of neurosis and psychosis, more especially those forms in which recovery is possible and those in which the mental symptoms are associated with organic disease in the nervous system or elsewhere The hospital itself deals with nearly 1 000 out-patients and 500 voluntary in-patients annually and can, moreover draw upon the mental hospitals of the County of London, which accommodate nearly 20,000 patients The following opportunities are open to medical practitioners and students without charge Dr W S Dawson is now giving a series of clinical lectures on Tuesday afternoons on the physical causes and accompaniments of mental disorders, Dr Edward Mapother lectures each Wednesday afternoon on mental symptoms and the mechanism of their development and Dr A A W Petrie, on Thursday afternoons on clinical mental syndromes These afternoon lectures commence at 2 30 Each Tuesday morning at 11 30 there is a discussion on cases in the hospital and on the last Friday of each month a monthly meeting at 4 p m of the medical staffs of the various mental hospitals of London at which each hospital in turn gives a demonstration of cases from its own wards The out-patient department is open on Mondays and Thursdays for male patients, and on Tuesdays and Fridays for female patients at 2 p m Appointments as clinical assistants are open, without fee to practitioners of either sex specializing in psychological medicine These posts can be either whole or part time and include work in the wards out-patient department or the laboratories as desired They may be held in conjunction with attendance at either of the courses for the diploma in psychological medicine or apart from this and they satisfy the requirements of the examining bodies for the D P M or for the M D in psychological medicine in respect of clinical experience of mental disorders Students may attend the clinical demonstrations required for their qualifying examination subject to the consent of the authorities of their own medical school, the Maudsley Hospital being recognized for this purpose by examining bodies

Medical Treatment of London School children

In making arrangements for the medical and dental treatment of children attending elementary schools and certain scholars attending secondary schools for the year beginning April 1st next, the London County Council has authorized provision for the treatment of 34 600 cases of eye defects 13,200 cases of ear, nose and throat defects 1 750 ringworm cases (the numbers of children suffering from ringworm are steadily declining) 67,000 cases of minor ailments and 120,000 dental cases The total number of cases is slightly in excess of those provided for in the previous year, and the total charge, £90 950 represents an increase of some £4,000 A scheme has been approved for dealing with children with discharging ears Five special inspection centres will be established to which children suffering from discharging ears will be referred for expert advice by one of the divisional medical officers who is an aural specialist and two half time assistants It has been decided to withdraw the grants to all the remedial exercise centres save one (at Woolwich) because the results obtained are held not to justify their continuation but the question of facilitating the extension of special daily physical exercise classes for children suffering from incipient and postural deformities is being considered For some types of deformity, when the children are unable to profit from attendance at an elementary school owing to their disability there is in London an abundance of provision at out-patient departments of hospitals, and one of the difficulties experienced by a number of voluntary remedial exercise and massage centres has been that of obtaining out-patients, because the hospital surgeons prefer to keep them under observation in their own departments The chief surgical causes of crippling found amongst London school-children are surgical tuberculosis and infantile paralysis It is stated that the provision made with regard to the first is satisfactory, and with regard to the second a complete scheme has been agreed to by the Council, in conjunction with the Ministry of Health and the Metropolitan Asylums Board for filling a gap which was found to exist in the provision for infantile paralysis cases

Correspondence.

THE PHYSICIAN'S OUTLOOK ON TUBERCULOSIS

SIR,—In the comprehensive and authoritative lecture on "Tuberculosis of the larynx its significance to the physician," delivered before the Royal College of Physicians of London on November 6th (BRITISH MEDICAL JOURNAL November 8th p 841), Sir StClair Thomson has justly pressed two points which are but insufficiently appreciated—namely, (1) the frequency in cases of pulmonary tuberculosis of associated laryngeal involvement in less or greater degree, and (2) the favourable outlook in respect of laryngeal tuberculosis when the condition has been early recognized

The grave prognosis we are compelled to give in many cases of laryngeal tuberculosis seen for the first time results inherently not from the character or localization of the disease, but from the fact that the laryngeal involvement has been determined only when the disease has made formidable headway

The position is much as it used to be in former days in respect of pulmonary tuberculosis Why was the prognosis in pulmonary tuberculosis thirty years ago—and even more recently—largely pessimistic In largest part because through ignorance of the natural history of the disease and the principles of preventive treatment the diagnosis was reached too late to be effective

With the widened outlook on tuberculosis which the past thirty years have brought, the physician is hardly just to himself or to his patient who does not proceed to the *examination of the larynx in every case of present or suspected pulmonary tuberculosis* Such examination determines immediately the presence or absence of laryngeal involvement In case of involvement early determination enhances much the chance of recovery under treatment Even in the absence of laryngeal tuberculosis, detailed inspection of mucous surfaces (buccal tonsillar pharyngeal and laryngeal) which laryngoscopic examination implies sometimes contributes considerably to the diagnosis in doubtful cases of lung disease

I have always held and taught that the physician is not entitled to conclude a diagnosis or prognosis in pulmonary tuberculosis without thorough examination of the laryngeal and contiguous mucous surfaces In most cases of suspected tuberculosis the up-to-date physician will go further Granted that there is evidence that a patient is suffering from tuberculous infection, he will feel it incumbent, to do

rest satisfied with the discovery of *one focus* of disease, but to investigate the various organs in succession, in order to determine precisely the extent and limits of tuberculous invasion Even when tuberculosis appears to be localized in one or other viscus, its import as a systemic disease—with further possible local outcrops at almost any point—must appeal to the scientific imagination and interest of the doctor He cannot nowadays content himself with the old view that tuberculosis present in a given organ constitutes, in any strict sense, a localized disease—I am, etc,

University of Edinburgh, Nov 8th R W Philip

CARBON MONOXIDE POISONING

Sir,—It is evident from various letters on carbon monoxide poisoning which have appeared in the Journal during the last twelve months that there is much difference of opinion as to the effects of inhaling this gas Two sets of statements are made which appear to me to be in conflict

We are told that carbon monoxide can only accumulate in the blood up to the saturation corresponding to its partial pressure in the air, and no further

The other statement is best defined by quoting from Rosenau's *Preventive Medicine and Hygiene*, p 1308, 1921 edition

"The poisonous properties of carbon monoxide are according to Haldane, due to the great affinity it has for the haemoglobin of the red corpuscles'

'It has from 140 to 250 times greater chemical affinity for haemoglobin than oxygen"

The first statement appears to me to lay down the principle that carbon monoxide behaves, as far as accumulation in blood is concerned, precisely as any other gas would behave If this is so, it does not matter what affinity carbon monoxide has for haemoglobin, it is beside the point, and pronouncements like Dr Haldane's quoted above become meaningless It is, however, difficult to accept this position because those of us who are familiar with industrial conditions of life can produce evidence that the inhalation of small quantities of coal gas is hurtful

Is it possible that the transient combination of CO with haemoglobin damages the latter, and leaves it damaged after the CO has been eliminated? It is desirable that some of our leading physiologists should give us a clear explanation of what actually does occur—I am, etc,

Macclesfield Nov 8th John N Laird, M D

TONSILLECTOMY

Sir—In his letter in your issue of November 8th (p 876) Mr F J Steward criticizes the resolutions passed at the Annual Meeting by the Section of Laryngology and Otology Surely some of his criticism is based on a wrong interpretation of the term "enucleation"

"Enucleation of tonsils" and "enucleation by dissection" are not synonymous terms Enucleation means the complete removal of the tonsil with its capsule This result can be achieved by several methods, of which removal by dissection is only one Tonsils can also be enucleated with the guillotine, by the snare, and by the Waring suction method

Since Whillis and Pybus published their epoch-making paper in 1910 guillotine tonsillectomy has been revolutionized This method was elaborated by Sluder in America and has been brought back to us as "the Sluder technic" It has now been developed to a very high degree of efficiency Sluder claims that after skill is acquired 99 per cent of tonsils can be enucleated by the guillotine Guillotine enucleation requires no more time nor anæsthetic than guillotine tonsillotomy It has many advantages over the dissection method, but it requires frequent and prolonged practice to acquire the desired skill in this method In a recent publication I have gone more fully into this subject[1]

To return to the resolutions of the Section of Laryngology and Otology, it is the old question of tonsillectomy *v* tonsillotomy The Section *unanimously* recommended tonsillectomy It is hard to realize that anyone can seriously think of going back to the old method of 'snipping a bit off the tonsil"—I am, etc

Guildford Nov 9th T B Johnson

[1] Tonsillectomy *Practitioner*, August, 1924

Sir,—I was very glad to read Mr Steward's letter in your last issue Is the guillotine operation to be entirely condemned? The difference between the guillotine operation and set enucleation is the difference between a minor and a major operation—if, indeed, any operation on the tonsil is ever a minor one

Undoubtedly most guillotine operations in competent hands are clinically successful But the occasional failure may well spell disaster to the operator, I own As a matter of fact cases requiring tonsillectomy differ so much in ease or difficulty that it is impossible to assess the operation at its proper value I believe myself that the problem could be solved by the invention of a properly designed guillotine What is wanted is a properly curved frame to sink in between the faucial pillars, act as a protecting frame, and a guide wherein to withdraw a flexible blade to excise the tonsil Is such an instrument possible?—I am, etc,

Sevenoaks, Nov 9th Gerald Sichel

PICRIC ACID ITS USE AND ABUSE

Sir,—I read with some interest the correspondence which appeared in recent issues of the Journal (September 20th and 27th) regarding picric acid dermatitis Dr Semon is anxious to absolve the dermatologist from having opened the door to this "yellow peril" among the antiseptics

Priority in the matter of its introduction is not of real importance, and at this date may be difficult to determine, but as long ago as 1889 Ceresi and Gaucher insisted on the value of picric acid in many inflammatory skin affections, apparently before it obtained a place in surgical therapeutics In 1896 Thiery, a Paris surgeon, advocated its use in the treatment of burns, and, impressed by his work, we tried it, presenting equally favourable conclusions in a thesis (1898) for graduation at Edinburgh In England Sir D'Arcy Power, in 1896, wrote of the use of picric acid that "a scar remains which is as much superior to the ordinary scar from a burn as our present surgical cure is superior to that obtained by our predecessors who allowed their wounds to granulate" In Scotland, Mr Miles said "Picric acid at least brings the burn into the condition of a healthy healing ulcer, more simply, more safely, and more rapidly than do other methods"

Supported by such strong opinions we cannot wonder that the value of this antiseptic was "widely promulgated in British medical literature"

But if picric acid is used on a burnt surface a definite method must be employed In the first place, Thiery's formula is Picric acid 12 grams, boiled water (tepid) 1 litre, allow to cool and decant Secondly, sterile gauze (never lint) is dipped in this solution, squeezed fairly dry, and applied to the burnt area The gauze is covered with a very thin layer of wool and fixed with a gauze bandage The value of this dressing is obtained from its rapid evaporation

In over twenty-five years' experience of picric acid in burns my partner and I have never seen the slightest dermatitis when it is applied in aqueous solution One case when a 5 per cent alcoholic solution was used as an antiseptic before operation on a breast case, dermatitis followed, curiously similar to the case mentioned by Dr Semon, the difference being that in our case the dermatitis appeared after the operation, not before But the alcoholic solution used elsewhere in the body for disinfecting the skin has never produced the slightest irritation in our experience

Picric acid, therefore, if used on burns, must be applied in aqueous solution, never in an ointment, never on lint

But the use of picric acid is not limited to the treatment of burns, for as a medium for preparing catgut the surgeon will find it most satisfactory For many years we have used a saturated solution of picric acid in clove oil for this purpose, as recommended by Roeder of Nebraska, with one slight modification Any variety of dry catgut, plain or medicated, is simply placed in this solution, where it remains indefinitely For use, the spools of catgut are transferred to absolute alcohol and are at once ready for use Personally we prefer chromic catgut, 6,0 or 3,0 for fine-ligatures and all gastro-intestinal work, and 1,0 or formalin strand for larger vessels, small pedicles, and suture of muscle and aponeurosis Prepared in this way

way the e types of catgut l come pliable, acquire considerable tensile strength and are perfectly antiseptic when manipulated with a gloved hand

We believe, therefore, that picric acid is still of considerable value in surgical practice But it re embles another valuable and powerful drug—chloroform—in this respect picric acid should never be applied to the skin, nor chloroform on a mask for anaesthesia, through the medium of that impermeable sub tance called 'surgical lint' The use of lint in either case iolates the essential principles on which their successful use depends—I am, etc,

Huelva Spain Oct 31 t. IAN MACDONALD, M D

SIR,—In view of the notes appearing in your issues of September 20th and 27th pp 520 and 569 with reference to picric acid dermatitis, the following case may be of interest

A woman aged 25 was admitted to the extern department of Dr Steevens s Hospital on Augu t 3rd 1924 suffering from a scald on the dorsum of the left hand This was dre sed at once with a 1 per cent aqueous solution of picric acid and subse quently daily with this dressing until August 24th when the left forearm became very sore and on examination was found to be marked all over the flexor surface with a linear dis coloration the long axis of which corresponded with that of the arm These marks were about 2½ inches long and about three eighths of an inch wide they resembled in appearance the con dition of the skin in burns of the second degree, after the bullae have burst

I saw the patient on October 17th and I thought the condition was due to the picric acid I obtained her consent to do a test on her right arm I did a cutaneous test with a similar solution of picric acid in a manner resembling the von Pirquet tuberculin reaction The next day there appeared a raised red papule about half an inch in diameter very tender to touch on the following day the lower part of the forearm presented an appearance exactly similar to the left forearm the entire right arm became gradually affected

The patient is still attending the hospital and seems to be much improved by her treatment with alcohol locally —I am, etc,

FRANCIS S BOURKE
Assi tant Pathologi t Dr Steevens s Ho pital.

Dublin Nov 3rd

THE IMPROVEMENT OF OBSTETRICS

SIR,—Dr Louise McIlroy's letter in your issue of October 4th and other letters in the issue of October 18th are full of interesting suggestions for the improvement of obstetrics but there is a curious conflict of views as to how improvement is to be obtained and the value of present methods for dealing with difficult cases Dr McIlroy sugge ts that *the midwife is rapidly cutting out the medical practitioner* and points out that 50 per cent of confinements are managed by midwives, whom she describes as 'a highly skilled body of specialists" The fact is that 50 per cent or even 70 per cent of all cases can be efficiently managed by a midwife because they require no management at all being normal cases and the less interfered with the better The remaining 30 per cent of cases are those requiring manage ment, and in this respect intelligent ob ervation rather than active treatment is required Nearly all complica tions occurring in labour present signs or symptoms at *the start of labour indicating that the condition is not* normal It may be difficult or even impossible for the most skilled specialist to say what the final result of some such cases will be the majority will be easily dealt with if recognized and treated at the proper time, instead of which as so often occurs, the early signs not being recog nized the ca e is treated as a normal one until actual difficulty or distress has developed The practitioner is then called in whether skilled or otherwise he is asked not only to treat the primary abnormality but to do so in spite of the further complications that have developed through neglect of the condition If the practitioner is skilled he may be able to make the best of a bad job, but as he is often little more skilled than the midwife, he is most likely to overlook the primary cause of the difficulty and concentrate on getting the case finished off as soon as possible by any means, and often the wrong means

Many general practitioners and midwives are highly skilled, and their skill chiefly lies in diagnosis, when they meet complicated cases they recognize them and, being wi e in their generation, they send such ca es into ho p al, where such treatment as is necessary can be applied when applicable Much of the difficulty in ob tetrics at pre ent ari es from the fact that in 80 per cent of ca es the patients are able to deliver themselves, and do so but since more than half the people conducting midwifery ca es are not capable of saying whether a ca e is normal or abnormal a large number of the remaining 20 per cent of ca es is mixed up with the 80 per cent At the start of labour each one of those 20 per cent or patient look and l, perfectly well and the amount by which they vary from the normal case may be very small but the variation is always there, and will prevent anyone with a proper know*ledge of the normal from cla ing the ca e as normal* The ignorant attendant does not recognize the variation or worse, having noticed it, thinks it is so little as not to matter and lets the ca e continue until di tress develop

There are a few but very few midwifery ca es in which labour starts normally and which do not terminate normally, with the exception of simple low forceps applica tion for the end of the second stage such cases never come to much harm In a moderate number of cases complica tions only develop in the third stage and here again the vast majority have early signs that the process is not progressing normally long before any symptom of the chief complication of the third stage excessive haemorrhage has developed A number of cases are, however allowed to continue in spite of the early signs until the patie its are suffering from actual lo s of blood So far as the midwife is concerned this is a ked for by the Central Midwives Board regulations, which instruct her to end for medical aid when there is exce ive bleeding' after two hours delay" That is not the time when aid should have been sought, help will probably arrive when the patient is moribund

With regard to ante natal management nearly all the complications of pregnancy develop gradually, and are amenable to treatment if treated early most are prevent able by maintaining a healthy mode of life Pregnancy is not a di ease, it occurs in health and generally as a result of good health Nevertheless the state of pregnancy upsets metabolism and the organs of metabolism may require a little help during pregnancy they must be pro tected from abuse and advice and guidance rather than treatment i what is required If a woman is found during pregnancy to be suffering from some condition which will cau e difficulty in labour she should be at the time of labour where that disability can be treated or such measures should be taken as will obviate the con equences of the disability She probably does not require any treatment during pregnancy Taking things all round diagnosis is what is required during pregnancy and labour rather than treatment There are ample means of placing any complicated ca e of pregnancy or labour under efficient treatment in the hospitals and infirmaries if only the abnormalities, or the probability of complications were recognized as soon as they are recognizable I this were done the midwives would not have complica ion becoming neglected and the practitioners would not be called in to treat debilitated patients nor allow their own cases to develop dystocia To effect this in practice it is neces ary to alter the present view of ob tetrics ta en by the public and the profe sion and to alter the lines of teaching My suggestions for this are as follow

Midwives should be taught normal labour and how to conduct a normal ca e This should include the ability to sa con fidently that a case is normal a the re ult of recognizing the characteristics of a vertex pre entation properly applied to the pelvic brim It the midwife cannot es ablish that act l palpation the case comes under the clas ification of Where no presentation can be made a o A malpr en ation I personally greatly doubt the ju ical lit of leaving a l l presentation to a midwife When a pre ening head is above the pelvic brim the condi on do not conte m th le normal start of labour 70 p r cent of ann ca ill spontaneous but leaving all uch ca es to e ha happen results in ol tructed labour in the le 30 p It is not necessary for the mid ife to d a e the particular abnormality it is sufficient f her to re ognize that the ca is no normal, and therefore hi n o the

province to conduct A midwife should be able to recognize that labour is progressing normally, when it ceases to do so *the case should be referred, instead of* waiting till distress sets in A midwife should hardly ever make a vaginal examination If labour is progressing normally none is required, if labour *ceases to progress* the fewer examinations made the better, if operative interference is required A malpresentation *can seldom* be diagnosed early per vaginam, and there will always be the facts referred to above to prevent the case being considered normal A midwife should understand the normal third stage and know exactly how to assist it, if it does not follow the normal course she should send for aid, and in the meantime simple methods of control will prevent excessive loss until aid arrives Those occasional cases of very rapid loss of blood *early in the third stage following* a normal delivery always occur *in multiparæ*, and there is always a history of a minor degree of the same complication happening in former labours This history should be obtained *by ante natal investigation, but the attending mid* wife is seldom unaware of the previous history, and the patient should be advised to go into hospital or have assistance *at the birth of the infant* The patient will never *object* when she is told that the complication can be prevented by early treatment and the risk of delay is explained To sum up, the duties of a *midwife should be to conduct normal labour* in normal cases, and be competent to recognize when a case is "not normal" It is quite unnecessary for her to diagnose the exact abnormality, or know the treatment, she may have a rudimentary knowledge of what is required if she knows what is wrong, but, is the treatment of any complication will vary with the associated conditions, she cannot be expected to know the proper treatment to be applied in the individual case

With regard to the training of midwives, a woman with no *previous medical training* is expected at present to be trained in six months If at the end of that time a woman has learnt to recognize and conduct a normal case, manage the baby and breast feeding, and do things with a reasonably safe degree of surgical cleanliness, she has done extremely well, and will be a safe midwife without being able to diagnose more than that a case is not a normal vertex presentation

Now, as regards the teaching of *obstetrics in the medical* schools, the student is expected to take practical obstetrics in his fourth or fifth year, but he has to fit it in as best he can with his other hospital practice There should be a definite period, say three months, at the end of the fourth or during the fifth year when the student would devote the whole of his time in hospital to the study of obstetrics, and during that time be excused from general hospital attendance During these three months a student should learn normal labour thoroughly and be absolutely confident in saying a case is normal and that progress is normal, or that a case is not normal or progress is not normal He should know at the end of his time how to conduct a normal case, manage the third stage, and how to examine thoroughly a patient to establish the fact that the case is normal or abnormal During the process of obtaining *this knowledge* he will meet a certain *number of* abnormalities and become cognizant of their characters, but, what is more important, he will learn to detect any cases which do not conform with the normal It is essential that a student *should conduct a number* of normal cases, since without doing this he can have no opportunity of learning the characteristics of the process In pneumonia the physical signs are present for days, and so a number of students can learn them and repeatedly observe them in a single case In labour the characters are *constantly changing, so that* even one student cannot repeatedly observe them, several cases are therefore required to teach one *case to one* student so that he will become reasonably cognizant of it In the same way instruction must be given in obstetric wards or hospitals, and *normal* cases are required for this instruction so that the student may be taught to palpate and practise diagnosis

With the present curriculum so little time is given to work in obstetric wards that nearly all or it has to be devoted to conducting labour cases, while the essential knowledge of diagnosis and prognosis is *neglected* The number of times a student is likely to see an abnormal presentation in three months is not sufficient to teach him anything of the individual conditions Take, for example the last report of Queen Charlotte's Hospital Confinements 1,779, breech presentations 83 transverse presentations 11, brow presentations 3, face presentations 2, on the other hand, there is no excuse for a student *not* learning all the characteristics of a normal vertex—1 702 cases Of course, in a number of these there were other complications 130 were contracted pelvis cases *The points indicating this* condition can be learnt and such cases be distinguished from frankly normal ones The treatment is seldom such as can justifiably be undertaken in a patient's home, but the condition can and should be recognized before labour or early in it

At the final examination a student should know normal labour as well as he is expected to know anatomy and physiology, should have a theoretical knowledge of *abnormal* labour and a thorough knowledge of the progress and management of normal labour so as to recognize any alteration as it develops When the student becomes qualified, if he wishes to take up obstetrics let him devote time to the further study of this branch in the same way as he would if taking up ophthalmology, pathology, or surgery

The general public require to learn that although the vast majority of confinements can be conducted by anyone with a small knowledge and the ability to recognize that the case is normal, the same person is not qualified to deal with an abnormality When the public learn this they will cease to ask the practitioner who looks after the family to treat the mother for abnormal labour, or, when the *midwife says she wants assistance*, be satisfied with the calling in of the nearest doctor or the family physician The general practitioner with a real knowledge of obstetrics in any district is the one who, from his special knowledge *sends patients into hospital at an early stage for treatment which cannot be carried out safely in the patient's home*

Dr McIlroy's suggestion of whole-time specialists is quite impracticable She points out that there are 700 000 *confinements in the year* in the extern department of the Rotunda about 2,000 cases are attended yearly, there are two extern assistants with the *hospital behind them* to supervise these cases, although many of the abnormal cases are weeded out during pregnancy and brought into hospital From my own experience as extern assistant I would not take it on as a life occupation, anyone who did so would be a lunatic or a drug maniac within two years The responsibility would be unendurable, to say *nothing* of the constancy and irregularity of the work At this rate something over 700 specialists would be required Where could they be obtained, and what would be their qualifications?

As it is, with the present obstetric hospitals and wards of hospitals in the large towns and the cottage hospitals and infirmaries in the country, there are ample means of dealing with abnormal midwifery—if the abnormal cases were recognized early instead of when *complications have* developed, and have to be dealt with as best can be in unsuitable surroundings, short-handed, and by someone who has never met a similar case before The present faults in obstetric practice will not be overcome *by a new body of* officials, nor by making the present midwives and doctors afraid to undertake anything because everything they do is to be scrutinized by a superior official *who probably has* no knowledge of obstetrics It can be overcome by teaching doctors, midwives, and the public the limitations of the *man* or woman midwife, and utilizing the present institutional facilities—I am, etc,

Rotunda Hospital, Dublin, Oct 18th GEORGE FITZGIBBON

RECTAL INJECTIONS OF SEA-WATER FOR THIRST

SIR,—Your article "In open boats," reviewing Captain Foster's book on his remarkable voyage, recalls to my mind some correspondence in the *Journal* six *and a half* years ago In the issue of February 16th, 1918 (p 220), appeared two letters, one based on actual experimental evidence advocating rectal injections of sea-water for the alleviation of thirst due to a lack of drinking water

I cannot at the moment put my hands on an analysis of sea-water showing its exact saline content, but what I want to know is Is hypertonic saline of a strength akin to salt water tolerated by *the bowel*, and will it be absorbed from it in the colon, as in the case of a *normal saline*, or will it produce, as in the case of purgative salts held in hypertonic solution in the intestine, a flow of fluid *from* the tissues *into the bowel*? *In* either statement is urgently *needed on these points*

If water can indeed be absorbed from hypertonic enemata, then surely steps should be taken to propagate knowledge to those who go down to the sea in ships It is dreadful to think of brave lives perishing in the midst of plenty Responsibility for a clear declaration as to efficacy or the reverse of such hypertonic solutions should rest with the medical profession—I am, etc,

W. BEVAN-BAKER

Reading, Oct 16th.

POST MORTEM EXAMINATIONS

SIR,—As a general practitioner of many years' standing I feel very strongly that a special department with paid medical officers should be created to conduct *post-mortem* examinations The medical officers might well be attached to boroughs or districts, and be paid by the State or the county council, as are the tuberculosis and health officers The usual *post mortem* examination made by the general practitioner is of little real value and, unless the cause of death is perfectly obvious, it is an extremely difficult procedure, requiring skill and technique which an ordinary practitioner cannot be expected to retain as years go on I believe that the valuable information gained by such expert examinations would benefit both the profession and the public The present system is wrong and antiquated this, if I remember rightly has been recognized long since in Canada where such a pecial department has been created —I am, etc ,

Horley Nov 2nd S A CLARKE, M R C S, I R C P

PERNICIOUS VOMITING OF PREGNANCY

SIR,—Dr Denver's account (September 13th, p 455) of a case of pernicious vomiting treated by lavage of the stomach and glucose in accordance with the theory of hepatic origin suggested by Duncan and Harding, is very interesting in the light of Cramer's[1] work on the action of insulin on the glycogenic function of the liver Cramer seems to have shown that the glycogenic function of the liver is an 'autonomous secretory function" which is inhibited by insulin and stimulated by thyroid and adrenal hormones

Glucose has been shown to be a safeguard against post-salvarsan jaundice, and someone has suggested insulin to combat the worst phases of acute hepatic crises (Unfortunately the reference to the latter suggestion has slipped my memory) The two methods seemed contradictory until the work of Cramer showed their connexion According to him the glycogenic function of the liver is continuous, whether there is carbohydrate to act on or not If no carbohydrate is available it converts protein into glycogen This glycogen is secreted into the blood as glucose at a rate depending on the concentration of glucose in the blood The introduction of glucose into the blood, therefore, whether directly or indirectly through the alimentary tract, would lessen the work of that organ in so far as it would obviate the necessity of secretion of sugar into the blood The administration of insulin over and above the use of glucose would still further rest the liver in that it would arrest its glycogenic function also The principle involved in both methods of treatment is therefore the same—resting the damaged organ, a principle well known in medicine

Personal opportunity has so far been lacking for the administration of insulin in hepatic crises, but among a number of patients at present under observation with disordered livers I hope soon to put the theory to the test It would be interesting to know if any general practitioner or hospital physician has yet used insulin in such cases —I am, etc ,

ASSISTANTS IN GENERAL PRACTICE

SIR —I have been an assistant in general practice now for five years during which time I have held two posts other than my present one I left my previous posts entirely on my own account as there were no prospects and I have excellent testimonials all through My present salary is £300

Owing to family calls on my limited income I have been so far unable to save sufficient capital with which to purchase a practice or even a share of one

I have been a member of the British Medical Association since starting in practice but I fail to see what it has done for the good of an assistant generally The Association has done some very excellent work for the profession in other ways but at the moment I feel constrained to advise all newly qualified doctors who intend to commence as assistants not to join the British Medical Association until they have at least completed the assistant stage

My first employer said to me You are very lucky there I was an assistant twenty-five years ago I only had £120 a year" But times have changed during the past quarter of a century For my next employer I had to sign a bond which excluded me (on leaving) from practice for ten years within a twelve miles radius from where I then resided I ascertained that such a bond was quite in order for a country practice, but why should it be so ridiculously stringent?

Let us hope that the very able suggestion of "F - Assistant" (October 11th p 690) will be carried out, and that the Association will investigate the conditions which he rightly refers to For our membership subscriptions we expect to get some consideration other than a copy of the JOURNAL once a week —I am, etc ,

October 25th. ANXIOUS

SIR —In view of the large number of newly qualified practitioners now joining the British Medical Association I think more attention should be directed to the conditions under which many of these have, owing to lack of capital to serve as assistant I notice in advertisements in the JOURNAL that the salary offered to some assistants is not mentioned, and I am aware of a case in which the post was given to the candidate willing to take the lowest salary Many assistants are ungenerously treated as regards off-duty, and are not later taken into partnership as it is cheaper to obtain a new assistant fresh from hospital

It is not a true comparison to declare the salary of a house-officer at a hospital enough for an assistant because the opportunities for learning are not the same How many practitioners take the trouble to teach their assistants anything?—I am, etc ,

November 2nd OXONIAN

THE GENERAL MEDICAL COUNCIL ELECTION

SIR —Will you allow me through your columns to thank the registered medical practitioners of Scotland for the expression of their confidence shown by my unopposed return to the General Medical Council as their Direct Representative?

It shall be my constant endeavour to continue to merit their trust —I am etc ,

Edinburgh Nov 11th NORMAN WALKER

Medico-Legal

CLAIM AND COUNTER-CLAIM

IN the Leeds County Court on October 3rd Dr J Logan of Chapeltown Road Leeds succeeded in recovering from Mr J Gilston of Chapeltown the amount of charges for professional attendance by Dr Logan upon the defendant's child and also resisted a counter-claim by the defendant who alleged negligence and unskilful treatment the jury being unanimously of the opinion that there had been no negligence whatever and that Dr Logan did his best in difficult circumstances

It appears from the reports in the *Yorkshire Evening Post* that Dr Logan diagnosed a serious bowel obstruction and advised a strict diet of breast milk for the baby The illness continuing Dr Vining of Leeds was called in and he whilst confirming Dr Logan's diagnosis suggested stomach washing which was carried out daily Dr Watson another Leeds specialist was also called in and approved this treatment but Mr Gilston being dissatisfied called in Dr Friend who adopted the method of administering cod liver oil by injection The child eventually recovered

Counsel for the defendant submitted to the jury that Dr Logan had been negligent in not adopting some form of treatment other than that which he said was not having the beneficial effect he hoped it would have upon the defendant's child The method of Dr Friend before the recovery of the child were recognised as ordinary feeding methods Nobody had suggested Dr Logan did not know them He admitted that Dr Logan was negligent because he did not take the advice of anybody for four weeks while the child was getting weaker and rejecting everything given in the ordinary way as food and because he did not resort to the method of feeding through the pores No child could vomit cod liver oil rubbed in through the pores of the skin

Judge Woodcock in summing up said there was no amount of man in the country however eminent who dared go into the box and swear that Mr Gilston's child would have died if it had not been treated by Dr Friend or that it was pure the treatment

[1] Cramer *Brit Journ of Exper Path* 1924 5 No 3 p 18

given by Dr Friend which resulted in its recovery It was just as likely that the treatment given by Dr Logan and approved by the specialists was the effective treatment in the case, because apparently it was usual for some time to elapse before improvement was noted It could only be a matter of opinion, and there could be no possible evidence either way

Dr Logan's case was undertaken on his behalf by the London and Counties Medical Protection Society

Universities and Colleges.

UNIVERSITY OF OXFORD

Scholarships and Exhibitions in Natural Science are announced for competition as under December 9th, 1924, at University, Balliol, Oriel Lincoln, and Magdalen Colleges, Christ Church, Trinity, St John's and Hertford Colleges, March 17th, 1925 at Merton, Exeter, New, Brasenose, Corpus Christi, and Wadham Colleges

The University has granted, by a decree of congregation, a sum of £3 000 towards the expense of providing a joint lecture room, library, and workshop for the departments of physiology and bio-chemistry

At a recent congregation the degrees of B M , B Ch were conferred on J W Alden

UNIVERSITY OF LONDON

Dr E Mapother has been recognized as a teacher of mental diseases at King's College Hospital Medical School and Mr Gerald R Lynch as a teacher of forensic medicine at Westminster Hospital Medical School

Mr H J Waring has been appointed to represent the University and King's College at the celebration of the fiftieth anniversary of the School of Technology of the University of Brussels this month

The University Medal in Branch I (Medicine) of the M D examination for internal and external students, July, 1924, has been awarded to John Norman Kerr, B S , an external student of St Bartholomew's Hospital, and the University Medal in Branch IV (Laryngology, Otology, and Rhinology) of the M S examination for internal and external students, July, 1924, has been awarded to Victor Ewings Negus, an internal student of King's College Hospital

UNIVERSITY OF BIRMINGHAM.

The Council of the University of Birmingham has decided to confer the title of Emeritus Professor upon Dr Thomas Wilson, late Professor of Midwifery and Diseases of Women

NATIONAL UNIVERSITY OF IRELAND

The following degrees and diplomas were conferred on November 3rd

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The annual meeting of Fellows and members will be held on November 20th at 3 p m at Lincoln's Inn Fields

We are informed that the following resolution will be moved by Dr W E A Worley and seconded by Dr M I Finucane on behalf of the Society of Members of the Royal College of Surgeons of England

That this thirty seventh annual meeting of Fellows and members again affirms the desirability of admitting members to direct representation upon the Council of the College moreover this meeting requests that the President shall hereupon reply in detail to the two resolutions passed at the last annual meeting and that he shall also state whether his Council has seriously considered any means whatever whereby the collective views of members of the College may be ascertained on matters affecting their interests as members

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following candidates have, after examination been duly admitted Members and Licentiates in Medicine of the College

A H Davidson, C J C Earl, R H Micks

V A Newton, having passed the required examination, has been admitted to the Licence in Midwifery of the College

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow on November 3rd the following officers were appointed *President*, Dr T K. Monro, *Visitor*, Mr J H Pringle *Treasurer* Mr J H MacDonald, *Honorary Librarian*, Dr E H L. Oliphant.

Obituary.

ALFRED JASPER ANDERSON, M A , M B , D P H, Formerly M O H Capetown

The death of Dr Jasper Anderson, late medical officer of health of Capetown, which occurred on October 2nd is deeply regretted throughout South Africa, and particularly by members of the British Medical Association of which he had been for many years one of the ablest and most loyal supporters

Alfred Jasper Anderson was born at Manchester in 1859 From Manchester Grammar School he went to Oxford, and studied medicine at St Bartholomew's Hospital London He obtained the diploma of M R C S in 1882 and graduated M B Oxon in 1883 He received the D P H Camb in 1888 He won the Radcliffe Travelling Fellowship at Oxford, and spent much time in Leipzig and Vienna After a period of general practice in Salford he took up Public Health work and became medical officer of health for Blackpool In 1901 he became the first whole time medical officer of health of Capetown and was responsible for the organization of the Health Department and its administration until his retirement, owing to ill health, at the end of 1922 Until last year he had held the professorship of hygiene at Capetown University He devoted himself enthusiastically to work in connexion with the British Medical Association, both in England and in South Africa, and, after holding various offices in the Cape of Good Hope—Western Province Branch, he became its president in 1909 He was a member of the Branch Council from 1909 to 1920, and represented the Branch at the Overseas Conference held in London in July, 1921 Dr Anderson was one of the original members of the South African Committee from 1911, and succeeded the late Sir Kendal Franks as president Until prevented by impaired health in 1922, he had been a regular attendant at the medical congresses In 1919 he was elected to the Colonial Medical Council, and remained a member of it until his death

He is survived by a widow, one son, who is a Major in the Indian Medical Service, and a daughter

Dr George Augustus Thompson of Darwen died from pneumonia on October 29th, aged 48 He was the son of the late Mr James Thompson, for twenty-five years head master of Holy Trinity School, Darwen, and was educated at St Mungo's College, Glasgow He took the triple Scottish qualification in 1899, and had been in practice in Darwen for the past twenty years He was a member of the Blackburn Division of the British Medical Association and of the Darwen Medical Society, of which he had been president and secretary During the war he served with a temporary commission in the R A M C , and was attached as medical officer to the Royal Field Artillery He leaves a widow and two sons

Dr Oliver H A Maggs of Haworth died on October 19th, aged 72 He was a native of Bourton, Dorsetshire, was educated at Uppingham School, and subsequently became a student at Charing Cross Hospital Medical School He took the diploma of L S A in 1892 and that of L M S S A in 1908 After practising in London and Horbury he went to Haworth, where he continued to practise for twenty-four years, until ill health caused his retirement He took much interest in public affairs, and was for eighteen years a member of the Haworth District Council, during which time he served on many committees He was second in command of the Keighley Volunteer Training Corps in 1915, and captain and second in command of the West Riding Volunteers From 1916 18 he was chairman of the Haworth Military Service Tribunal, and was visiting radiographer at the Keighley and Bingley Hospital Dr Maggs, who was honorary anæsthetist to the Victoria Hospital, Keighley, was appointed a justice of the peace for the West Riding of Yorkshire some three or four years ago He was a member of the Bradford Division of the British Medical Association He is survived by a widow and a son

Medical News.

THE next session of the General Medical Council will commence on Tuesday, November 25th when the president Sir Donald MacAlister, Bt, K C B, M D, will take the chair at 2 p m and give an address

THE twentieth South African Medical Congress will open on July 6th 1925, at Pietermaritzburg The president is Dr D Campbell Watt, the treasurer Dr A W H Cheyne, and the general secretary Dr C G Kay Sharp, Education Department, Pietermaritzburg The secretaries of the sections are as follows Medicine and Mental Hygiene, Dr W J May, Surgery Dr H T Rymer Obstetrics and Gynaecology, Dr H E Allanson Public Health Dr Nellie Wall Mesham Special Subjects, Dr E W Ingle Early notification of intention to read papers should be sent to the secretary of the appropriate section

THE annual dinner of past and present students of the Royal Dental Hospital of London will be held at the Trocadero Restaurant on Saturday November 22nd, at 7 o'clock with Mr W Warwick James O B E, in the chair

THE staff of the Royal Dental Hospital of London will hold their annual clinical 'At Home' at the hospital Leicester Square W C 2 on Saturday November 22nd, at 2 p m Cases of special clinical interest which have come under observation and treatment during the past year will be shown and demonstrations given The various departments of the hospital will also be open for inspection The medical committee extends a cordial invitation to any medical practitioners who may like to attend. Tea will be provided

LORD DAWSON OF PENN G C V O M D will read a paper before the Insurance Institute of London on Monday November 17th on the need for extended sickness insurance The place of meeting is the lecture theatre of the School of Oriental Studies London Institution, Finsbury Circus, and the time 5 30 p m

THE Institute for Clinical Research at St Andrews Fife, has arranged for a series of papers on renal efficiency to be read on Tuesday afternoons at 4 o clock The first was on Tuesday last when Professor Herring dealt with the physiology of the kidney he will continue his discussion of this subject on November 18th Dr Hynd will discuss the chemical constitution of the urine and blood in health and disease on November 25th and December 2nd and Dr Macfennan the clinical pathology of the urine on December 9th and the pathology of the kidney on December 16th All practitioners are cordially invited to the lectures

AT the meeting of the Hunterian Society to be held at the Cutlers Hall Warwick Lane E C, on Monday next November 17th, at 8 45 p m a discussion on the medical witness will be opened by Mr Justice Horridge and Sir William Willcox K C I E The following are expected to take part Sir Francis Newbolt K C, Sir E Marshall Hall K C Sir Bernard Spilsbury Mr J A. Cairns (Magistrate Thames Police Court), Mr Freke Palmer, and Dr Spurgin

A CHADWICK public lecture on Smoke cause nature effects, and methods of prevention (illustrated by lantern slides) will be given by Professor J B Cohen Ph D, F R S on Wednesday, November 19th at 8 p m at the Royal Institute of British Architects, 9 Conduit Street London W

THE annual general meeting of the Medical Officers of Schools Association will be held at 11 Chandos Street, W 1 on Friday, November 21st at 5 p m (tea, 4 30 p m) when the president Dr L R Lempriere, will read a paper on preventive hygiene in public schools, based on twenty years experience

THE first meeting of the session of the Yorkshire Tuberculosis Society was held at the Sheffield Tuberculosis Dispensary on October 25th Dr Rennie took the chair, and a paper on surgery in the treatment of pulmonary tuberculosis was read by Dr H Morriston Davies superintendent of the Vale of Clwyd Sanatorium

THE Langley Memorial Prize of the London School of Hygiene and Tropical Medicine has this year been awarded to Dr P S Selwyn Clarke, M C D P H, of the West African Medical Service for his monograph on small pox in the negro and negroid tribes of British West Africa, with special reference to the Gold Coast Colony The prize was founded by the friends of the late Dr W H Langley C M G, Principal Medical Officer of Southern Nigeria, to commemorate his work and this is the first year of award

THE Harben Lectures which were to have been given on November 24th 25th, and 27th by Professor Edgar L Collis, M D, on phthisis and industrialism (national and occupational) with reference to other infectious diseases, have unavoidably been postponed

THE seventh, eighth, and ninth lectures of the series on cancer open to members of the profession and arranged by the Fellowship of Medicine, will be delivered in the West Lecture Hall at 5 30 p m on Monday November 17th by Mr Cyril A P Nitch on 'Cancer of the Intestines' on Wednesday November 19th by Mr W Sampson Handley, "Cancer of the Breast" and on Friday November 21st by Mr H. S Souttar, Carcinoma of the Oesophagus The Chelsea Hospital for Women has arranged a special course from November 21st to December 8th. A four weeks course, starting on November 24th, will be given at the Royal Waterloo Hospital for Children and Women, in medicine surgery, and gynaecology, with special reference to diseases of the blood, nervous system heart diseases, feeding of infants etc During the first fortnight in December the Royal Northern Hospital, in conjunction with the Royal Chest Hospital will hold an intensive course in medicine surgery and the special departments the Infants Hospital a course on the study of infants and the Hospital for Diseases of the Skin (Blackfriars), a short course in dermatology, including venereal clinics Copies of the syllabus of each of the above mentioned courses may be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W 1

DR GRENVILLE MACDONALD will give a public lecture on "Octavia Hill her personality and inspiration, at the Royal Society of Arts 5, John Street Adelphi, W C, on Thursday November 20th at 5 p m

AT a meeting of the National Baby Week Council, on November 12th, a discussion on propaganda work in connexion with ante-natal care was opened by Dr F Watts Eden, who dealt with the relation of ante natal care to maternity and child welfare Miss Hester Viney honorary secretary of the Public Health Section of the College of Nursing spoke on propaganda among mothers and Mr E B Turner F R C S raised the question of the fathers Dr Vincent Denne dental surgeon of the Infants Hospital, Westminster, opened a discussion on propaganda in favour of extending dental clinics for nursing and expectant mothers and for children under 5 At the end of the meeting the council's new film, The work of an infant welfare centre, was exhibited

APPLICATIONS for the year 1925 for the Government grant for scientific investigations must be received at the offices of the Royal Society not later than January 1st They must be made on printed forms obtainable from the clerk to the Government Grant Committee, Royal Society Burlington House W 1

THE following are among the medical men elected on November 10th to the office of Mayor Dr G R Anderson (Southport) Alderman Dr C W Buckley (Buxton) Alderman Dr W J Cale (Bury St Edmunds) re elected Dr H J Campbell (Dartmouth) re elected Alderman Dr J W Clegg (Burnley) re elected, Alderman Dr W I Fern J P (Congleton) re elected Alderman Dr O W Griffith J P (Pwllheli), re elected Dr E J Toye (Bideford) As already announced, Dr G S Pope has been elected Lord Mayor of Norwich

THE College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, amounting to about 300 dollars will be made in 1925 Essays may be upon any subject in medicine but cannot have been published they must be typewritten and in English and they must be received by the Secretary of the College 19 South 22nd Street Philadelphia U S A on or before May 1st 1925 Each essay must be unsigned but marked with a motto and accompanied by a sealed envelope having on its outside the motto and within the name and address of the author The prize for 1924 has been awarded to Dr Gordon Cameron of Victoria Australia for his essay on pancreatic anomalies

DR WILLIAM BUSBY COLLTEP senior medical officer has been appointed an official member of the executive council of the presidency of Montserrat.

THE Right Hon Neville Chamberlain M P Minister of Health has appointed Mr Douglas Veale to be his private secretary and Mr A Noyil Rucker assistant private secretary

---

WE have to announce with deep regret that Dr G E Hislip died on the afternoon of Wednesday November 12th after a long and painful illness For eight years—from 1916 until last June—Dr Hislip held the office of Treasurer of the British Medical Association and devoted his time and energies with characteristic abilities to the [illegible] of the Association's building [illegible] publish a memoir in our next issue The [illegible] funeral service will be held at St Martin-in-the-Fields Trafalgar Square to-day (Friday November 14th) at 11 o'clock, the cremation at Woking Parish Church

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS *forwarded for publication are understood to be offered to the* BRITISH MEDICAL JOURNAL *alone unless the contrary be stated* Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W C 2, on receipt of proof

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W C 2 Attention to this request will avoid delay Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 129, Strand, W C 2

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange) The telegraphic addresses are

EDITOR of the BRITISH MEDICAL JOURNAL, *Articulate Westrand, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc) *Articulate Westrand, London*

MEDICAL SECRETARY, *Mediocre Westrand, London*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus Dublin*, telephone 4737, Dublin) and of the Scottish Office, 6 Rutland Square, Edinburgh (telegrams *Associate, Edinburgh*, telephone 4361 Central)

QUERIES AND ANSWERS.

EPILEPTIFORM FITS

DR P MERRIN (Mount Clarence, Kingstown) writes If "H C B" (November 8th, p 883) will try bromocamphin one teaspoonful in water three times a day before meals and 1/2 grain thyroid extract twice a day after food he will find it of advantage to his patient

SUGGESTION DURING SLEEP

"EXPATRIATED" asks for detailed information, or a reference to literature containing it on how to employ the method of suggestion during sleep in order to assist a child of 13 to overcome certain weaknesses These include a stoop, for which regular exercises are being done, and a weak memory Suggestion might, he thinks, be valuable also in removing a dislike to a language the child is learning, the lessons in which are easy in themselves The father, a medical man, wakes the child every morning, he wishes to know how long a time should elapse between the making of the suggestions and the waking up of the child

LIQUID PARAFFIN AND CANCER

DR A C JORDAN (London) writes in reply to "B K" (November 1st, p 840) and DR S Watson Smith (November 8th, p 884) (1) Crude industrial oils contain irritant impurities, these cause cancer (2) Medicinal paraffin, properly purified, is free from all irritant impurities, it is quite incapable of causing cancer Hence one question only need be asked "Are all medicinal paraffins pure?" The reply is, "Yes, all those that are colourless, odourless, and tasteless" So far from causing cancer medicinal paraffin undoubtedly prevents cancer by rendering the faeces soft, pliable, and non irritant

STERILIZATION OF HYPODERMIC OUTFIT

"E H" writes Reading the letter in your issue of November 8th (p 884) by Dr W Johnson Smyth, on rapid sterilization of hypodermic syringe and needle, I would like to inquire if it is quite 'safe" to use one of the outfits on the market in which the syringe is kept immersed in an antiseptic fluid The fluid advised is absolute alcohol, but this being so expensive I have substituted methylated ether and even petrol Both of these evaporate so readily that it is not necessary to wash with sterile water

INCOME TAX

Change of Practice—Cash Receipt

"A W" sold his practice at the end of September 1923 He is now being asked by the inspector of taxes for a statement of account showing the amount of his cash profits for his last six months in order that his successor may be correctly assessed, and also for a statement as to the amount of cash recovered since the practice was sold in order that he may be charged to tax thereon

*** As regards the first point if "A W" does not now possess the necessary records his only course is to try so and leave his successor to come to some arrangement with the inspector as to the assessment It is of course unfortunate that the particulars necessary for a correct assessment are not available The second point is more serious in its application and has been dealt with in this column more than once The inspector's suggestion that A W is liable to account for tax on cash received for past debts involves a misapprehension of the position He is not liable to assessment in respect of professional earnings receipts for such periods as he was in the practice which earned those debts It is true that in the past he has paid tax on the basis of the cash received, but that was in reality because, as a matter of mutual convenience, the amounts so received were taken as equivalent to the true gross receipts—that is, to the value of the year's bookings

LETTERS, NOTES, ETC

THE DOSE OF TRYPARSAMIDE

PROFESSOR C H BROWNING (Glasgow) writes with reference to paragraph 358 on page 66 of the *Epitome* in our issue of November 8th, and suggests that there must be a serious mistake in the recommendation of 5 to 15 grams as the dose of tryparsamide for daily intravenous injection In his experience the maximum single dose intravenously is about 0 3 gram He adds that such administration would lead to serious results

*** The doses given in our abstract were those recommended by the two writers of the original article

ELECTRIC SHOCK

DR J O'C FITZSIMONS (Blaina, Monmouthshire) writes At a Hackney inquest recently on a man who died from heart failure consequent upon an electric shock Dr R M Bronte said there was a case recorded in America where 20,000 volts passed through the body without causing death I had a case recently in which 20,000 volts at a colliery passed through a man He recovered consciousness after twenty minutes' artificial respiration He was none the worse after a few days, except for a large piece of flesh which sloughed from the sole of one of his feet He was standing at the time of the shock on a dry concrete floor, but totally unprotected as regards gloves or rubber shoes

ARSENIC IN URINE

MR H E COX PH D, M SC, reporting on November 5th to the Society of Public Analysts, said that the inquiry of the Swedish Commission into chronic arsenical poisoning had been carefully tested and the conclusion had been reached that the nitric and sulphuric acid digestion process described by Bang and Ramberg gave higher and more accurate results than the older wet combustion method adopted by the Joint Committee of the Society of Public Analysts and the Society of Chemical Industry in 1902 It was found that normal urine might contain quantities of arsenic which had been thought to be associated only with chronic arsenical poisoning, the amounts present in the urine of persons on known diets varied from 0 0 up to 0 53 mg per litre An increase in the excretion of arsenic was traceable to the eating of fish, and it had been shown that fish, especially plaice, might contain arsenic up to three parts per million The eating of such fish led to the appearance of arsenic in the urine within twenty four hours

THE M D BRUX DEGREE

DR ARTHUR HAYDON (2, Crossfield Road, N W 3), Hon Secretary, Brussels Medical Graduates' Association informs us that he has recently had interviews with the University authorities in Brussels regarding the M D degree for foreigners He has ascertained that all candidates will be required to submit their degrees or diplomas for consideration to the Secretary of the University, and be prepared to spend at least one year at the University by attending the lectures, clinics, and practical work before being allowed to enter for the examinations These are conducted in French, viva voce The degree does not confer the right to practise in Belgium The period of residence required will vary according to the standard of the diploma submitted by the candidate for the consideration of the University authorities The fees for the year are Courses, 525 francs, laboratory 250 francs, examinations, 110 francs

MISSING NUMBERS

DR J ALLMAN POWELL, Hon Secretary, Cheltenham Medical Library, writes I am anxious to obtain the following copies for the *Lancet* to complete the collection of this library July 7th, 1919, December 6th, 1919, February 7th, 1920, March 6th, 1920, April 10th 1920, October 23rd 1920, November 5th 1921, August 26th, 1922, May 12th, 1923, May 24th, 1924 I would be very grateful if any of your readers could let me have any of these numbers

CORRECTION

DR MORRIS J COHEN (Liverpool) calls attention to the incorrect spelling of his name in the reports of the discussion on post-operative pulmonary embolism published in the JOURNAL of August 2nd (p 184) and November 8th (p 856)

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical corporations and of vacant resident and other appointments at will be found at pages 38 37 40 and 41 of our advertisement columns and advertisements as to partnerships, etc, and locumtenencies at pages 33 and 39

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 157

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

373 Intracranial Aneurysm

R LITZ (*Boston Med and Surg Journ*, September 18th, 1924 p 521) states that cerebral aneurysm is not a remarkably rare condition, Beadles (1907) collected particulars of 505 cases Fitz refers to recent papers by Charters Symonds and Harvey Cushing, who have described a fairly typical clinical syndrome found in many cases The symptoms may be threefold (A) Pressure symptoms referable to the base of the brain or the outer wall of the cavernous sinus (B) Symptoms due to the systemic disease which caused the aneurysm (C) Symptoms due to leakage from the sac In Class A Symonds includes (1) pain in the region supplied by the first division of the fifth nerve, paresis or paralysis of the third fourth, and sixth nerves, exophthalmos and amblyopia due to pressure on the optic nerve In Class B are symptoms of cerebral arterio sclerosis or, more rarely, of infective endocarditis Fearnsides (1916) stated that syphilis was an exceedingly rare cause of cerebral aneurysm In Class C are sudden headache or backache followed by syncope The cerebro spinal fluid is blood stained and relatively large fundal haemorrhages occur frequently Cushing states that aneurysm should always be suspected when one or more sudden apoplectic attacks are followed by symptoms relating to the intracranial portion of the internal carotid If there is subhyaloid haemorrhage or blood in the cerebro spinal fluid the diagnosis is comparatively obvious Fitz reports a typical case in a woman aged 43, who had had one child no miscarriages and whose Wassermann reaction was negative She had a history of eclampsia, convulsions, and Caesarean section Evidence of high blood pressure was present at that time this persisted, and more than two years before death there was oedema of the ankles and high blood pressure In October 1923 she had a sudden attack of unconsciousness with vomiting and epileptiform convulsions On recovering consciousness the left eye was blind and the right amblyopic Oedema of both discs was present, more marked in the right, and with evidence of old and recent haemorrhages more plentiful in this eye Three months later she complained of frequent headache and was easily fatigued The systolic blood pressure was 190 mm the diastolic 110 mm, and the second aortic sound was loud and ringing In the urine there was a faint trace of albumin, a little renal epithelium a few red and white corpuscles and hyaline casts Three months later she had a second attack of sudden unconsciousness with generalized convulsions On recovering consciousness there was no paralysis, but tendon reflexes were absent, there was no ankle clonus, and Babinski's, Oppenheim's and Kernig's signs were absent The blood count showed excess of red corpuscles (7,420 000) and of leucocytes (33,700) the haemoglobin percentage was 135 The urine contained albumin, a small trace of sugar, red and white cells and a moderate number of granular casts On lumbar puncture 35 c cm of uniformly blood stained fluid under great pressure escaped she then regained consciousness rapidly, but a partial lower facial paralysis was observed Stupor returned and she died twenty four hours after admission The necropsy showed the entire right cerebral hemisphere covered by dark red clot, except for a small area on the anterior surface of the frontal lobe There was a sacculated aneurysm of the right internal carotid, which measured 16 mm by 13 mm and had ruptured this pressed on the chiasma and the right optic nerve With the exception of absence of unilateral oculo motor paralysis and occipito frontal pain all the symptoms corresponded with Charters Symonds's and Harvey Cushing's descriptions in *Guy's Hospital Reports* (April, 1923)

374 Melaena Neonatorum

D V RAISZ (*Zentralbl f Gynäk* July 12th, 1924, p 1550) points out that melaena neonatorum is not a clinical entity, but is a symptom of many diseases during infancy Having satisfied himself that the milk supply was uncontaminated he examined the stools of infants during the first three days of life, and in a series of 53 cases detected blood present in 34 He therefore holds that in a large number of newly born children there is occult bleeding from the bowel the infants being in no other sense abnormal He thinks that such bleeding can be considered as physiological rather than pathological, and that it may be compared with the catarrh of the newly born, which, beginning on the third day when the colostrum is replaced by milk, is a manifestation of the activity of milk borne flora Remembering the delicacy of the mucous membrane of the bowel he adds, it is no surprising that this milk invasion followed by the inevitable bacterial activities should produce a hyperaemic or even a haemorrhagic reaction in the bowel melaena neonatorum is only a further degree of this reaction due to an additional endogenous or exogenous factor

37 Purpura in the Serum Disease

L PITAP (*These de Paris*, 1924, No 419) reviews the literature and classifies the varieties of purpura occurring during the serum treatment of diphtheria in the following three groups In the first group purpura appears in the form of ecchymosis at the site of injection Several cases of malignant diphtheria belong to this group in which the purpura is of diphtheritic origin The second form of purpura in the course of diphtheria occurs at the time of the serum disease The lesions of purpura are closely intermingled with those of the serum eruption, especially urticaria, and are often associated with a scarlatiniform or morbilliform erythema Pitar records two examples of this group, in which the purpura is probably due to streptococcic septicaemia The third form of purpura is associated with an urticarial eruption but the blood culture is negative In this variety of which Pitar records one example, the purpura is entirely due to serum disease, being merely a further stage of the capillary dilatation which ordinarily accompanies this condition

376 Nephritis due to Tuberculosis

C HOLTE (*Ugeskrift for Laeger*, September 18th and 25th, 1924, pp 687 and 711) has investigated the frequency with which nephritis of tuberculous origin occurs among the subjects of pulmonary tuberculosis He notes that it is difficult to establish a definite connexion between pulmonary tuberculosis on the one hand and inflammatory but not specifically tuberculous, changes in the kidney on the other His material was obtained from his hospital, in which 1 200 to 1,400 patients with pulmonary tuberculosis are treated every year In the period 1917-21 there were 3 619 cases of pulmonary tuberculosis, 20 to 25 per cent of which were readmissions Among them there were 124 cases of albuminuria nephritis and amyloid disease In 45 cases there were reasons for believing that the renal disease though not tuberculosis, was the outcome of the pulmonary tuberculosis These 45 cases could thus be classified haemorrhagic nephritis 12 haemorrhagic nephritis with amyloid dis ase 3 amyloid disease 23, amyloid disease complicated by renal tuberculosis 4 transitory albuminuria 2, granular kidney 1 The author concludes that amyloid disease is the most common of the non specific renal complications of pulmonary tuberculosis, and that haemorrhagic nephritis comes next in frequency

Surgery.

377 The Prognosis in Perforation o Gastric and Duodenal Ulcers

O E CEDERBERG (*Finska Läkaresällskapets Handlingar*, July-August 1924 p 636) has collected 71 cases of operation for perforation of gastric and duodenal ulcers in his hospital in Wiborg from 1904 to 1923 Only 2 of these patients were females, and in 10 only was the duodenum perforated in the remaining cases the pyloric end and the lesser curvature of the stomach were affected In 30 cases the treatment consisted of simply closing the perforation and performing Braun's omentoplasty The mortality in this class was 50 per cent, the length of the interval between perforation and operation being chiefly responsible for this poor result Since 1914 gastro-enterostomy was often performed in addition to closure of the perforation, and among 37 cases thus treated there were only 6 deaths The following figures show how important it is to operate early Of the 17 patients operated on within six hours of perforation all recovered of 14 operated on from six to twelve hours after perforation 85 7 per cent recovered of 13 operated on from twelve to eighteen hours after perforation 71 4 per cent recovered of 7 operated on from eighteen to twenty four hours after perforation 42 9 per cent. recovered and of 15 operated on more than twenty four hours after perforation only 20 per cent recovered An investigation of the subsequent fate of the patients showed that only 30 per cent of those who had been treated by simple closure of the perforation were in good health, whereas this was the case with 60 per cent of the patients on whom gastro-entero tomy had been performed as a supplementary operation.

378 Spina Bifida and Meningocele

T. S Klots (*Nederl. Tijdschr v Geneesk.*, August 16th, 1924, p 884), who records an illustrative case, states that Brickner classifies the conditions associated with a defect in the vertebral arch as follows (1) Complete closure of the vertebral defect by a more or less dense connective tissue membrane, usually associated with adhesions to the superjacent soft parts and skin (2) A band of connective tissue perforating the membrane and connecting the subcutaneous tissue with the spinal membranes so as to exercise a pressure on the cord (3) Compression of the cord or its nerves by (*a*) an excessive growth of fatty tissue within the membrane, (*b*) a myofibrolipoma penetrating the spinal canal through the defect in the bony arch, (*c*) an exostosis in the spinal canal (4) A degeneration or aplasia of the spinal nerves (5) A protrusion of the dura through the defect leading to meningocele (6) Hypertrichosis is frequently found, but its presence does not always indicate spina bifida (7) Incontinence of urine is the rule in children and is often present in adults (8) Pain, either localized or radiating into the legs, is less frequent The most favourable time for operation is between 9 months and 2 years Before the age of 9 months the mortality from the operation is very high, and after two years the prognosis is more unfavourable because the meningocele may increase in a large number of cases and the chances of perforation are greater In adults the operative mortality is particularly high because generally the tumours round the sac become infected, so that operation should not be performed on adults unless the tumour is very large and is giving rise to distressing symptoms Progressive hydrocephalus worsens the prognosis of operation for meningocele, the mortality in such cases being 50 per cent It is therefore advisable when possible to wait till the end of the second year because the hydrocephalus may often become stationary of itself within the first two years of life If an operation is undertaken during the presence of hydrocephalus puncture of the corpus callosum should be performed ten days before the operation

379 Diverticulitis of the Colon

E S Judd and L W Pollock (*Annals of Surgery*, September, 1924, p 425) point out that diverticulitis of the colon deserves consideration because of the frequency with which it is encountered and the severity of the symptoms manifested There may be a solitary diverticulum in the colon, or a great many diverticula from the caecum to the rectum In many cases the condition causes no symptoms and it is apparently not progressive It is a disease of middle life and is usually seen in the sigmoid In diverticulitis an abscess may form and later perforate into the intestine, bladder, or abdominal wall If the inflammation remains chronic a tumour composed of fibrous tissue and the products of inflammation develops The authors remark that it may be difficult to differentiate between diverticulitis of the sigmoid and a carcinoma If there is a long history and the tumour has increased and receded from time to time it is probably due to a diverticulitis In some cases a diagnosis can only be made after histological examination If an abscess forms drainage is indicated, and if perforation occurs operation is the only procedure that offers relief The mortality from radical operation has been high The plan of procedure recommended is a preliminary colostomy to relieve any obstruction in the colon, and the reduction of the inflammation by frequent irrigations of the lower colon The infected portion can then be resected with less risk

380 Extensive Skin Regeneration without Grafting

R I Hertzberg and G R R Hertzberg (*Amer Journ of Surg* September, 1924, p 236) describe a method of covering a denuded surface with a layer of epithelium, which consists essentially across the wound from the skin edges at the rate of about 1/32 inch a day The wound is first treated as though a skin graft were to be applied—that is, a healthy granulating wound is essential This is washed with commercial petrol, which is then lightly dried with gauze and the edges painted with a mixture of equal parts of Peru balsam and castor oil The wound is then lightly encircling but not with sterilized adhesive strips in such a manner that on the skin edge is the streak of balsam and complete apposition with no puckering The crossing the open area Firm pressure is important thing, and there must be no movement of the wound is dressed with the method especially centre of the wound is dressed with dichloramine T in chloreo ane The patches assert that pected daily The authors find this method valuable in the treatment of large burns for its healing is very rapid and that there is no contraction

Therapeutics.

381 Emetine in the Treatment of Amoebic Abscess

A S Ibn (*Indian Med Gazette*, October, 1924, p 483) records two cases of large amoebic abscess of the liver in which complete cure of the patients was obtained by the hypodermic administration of emetine hydrochloride In both cases the remedy was injected daily in 1 grain doses until 12 grains had been administered In one case the effect was dramatic, the temperature falling to the normal after the second injection and remaining steadily subnormal thereafter In the other case improvement in the temperature did not occur until the end of treatment In both cases coexistent helminthic infections required eradication Fry maintains that the induced spontaneous absorption of the large sterile abscess is in no way detrimental to the patient, but that, on the contrary, the general health improves concurrently He believes that aspiration is unnecessary in many of these cases, and recalls the instructive analogy drawn by Sir Leonard Rogers between tuberculous and amoebic abscesses

382 Iodine and Hyperthyroidism

S J Cowell and E Mellanby (*Quart Journ Med*, October, 1924, p 1) studied the effect of iodine on hyperthyroidism in man They kept careful records of the basal metabolic rate, pulse rate, weight, neck measurement, and general condition in eight patients, each of whom received a standard diet of about 1,800 calories, with the administration of potassium iodide in varying amounts and intervals Small doses (1/10 grain daily) produced a lowering of the basal metabolic rate and clinical improvement which reached a maximum in from ten to twenty days This was followed by a gradual return of symptoms, though not to the former extent, and withdrawal of the iodide after several months' treatment resulted in an exacerbation of symptoms, which, however, were relieved by a further administration of iodine While apparently not curative, the authors find the treatment useful as an adjunct to other medical treatment and as a preliminary to operation Those patients best withstood operative treatment in whom the iodine content of the thyroid was high The response to iodine therapy resembles that following operation, in that periods of "primary improvement" and "relapse" were noted in those cases treated by iodine to be like those seen in exophthalmic goitre treated by operation Apart from the fact that iodine is a constituent of thyroxin, the way in which it influences metabolism is not yet understood The authors think that it is not possible to predict its effect in any given case, though patients with large hard thyroids seem more likely to develop reaction symptoms than those with smaller and soft ones Within certain limits the actual amount of iodine given does not appear to influence the rate of improvement, yet with very small doses the return of symptoms tends to be longer delayed and less severe than when larger doses are given

383 Sodium Thiosulphate Treatment of Metallic Intoxication

Marion R Groebl and C N Myers (*Therap Gaz*, October 15th, 1924, p 691) report fully on some 75 cases of arsenical poisoning benefited by sodium thiosulphate The two most serious conditions arising from the continued use of salvarsan are arsenical dermatitis and jaundice A 0·4 per cent solution of sodium chloride injected intravenously was found to diminish the risk of the uneven distribution of the soluble colloidal arsphenamines in the tissues Concentrated solutions of glucose or lactose were also used as the diluting medium, 2 to 4 grams of the sugar being best tolerated Sodium thiosulphate was found to be still more useful, and was also used in mercury and lead poisoning The thiosulphate had a low toxicity, and could be given either by the mouth or intravenously, the latter method being found to be more efficacious in stimulating the excretion of the metal 30 grains by the mouth could be given per day In nearly their cases the authors determined the amounts of arsenic in the blood, urine, and in epidermal scales before and after the administration of the thiosulphate Details of three cases are given, the first being dermatitis exfoliativa following arsenical treatment for xeroderma kaposi, the second xeroderma due to skin absorption of arsenic from fur, the third poisoning by illicitly distilled spirit ("moonshine") The authors state that the salt stimulates the excretion of arsenic both through the kidneys and the skin but that freshly prepared solutions should be used A bibliography of thirteen papers is given.

384 Hyoscine Treatment in Post encephalitis

L B HOHMAN (*Johns Hopkins Hosp Bull*, October, 1924, p 335) reports eighteen cases of the Parkinsonian syndrome following epidemic encephalitis in which hyoscine hydrobromide treatment was administered with considerable success The average dose was 1/100 grain four times a day, and the maximum 1/50 grain In no case was it necessary to increase the dose as the result of tolerance being acquired No bad effects were observed except that some slight difficulty in accommodation, giddiness, and somnolence occurred whilst the dosage was being regulated As soon as the effective therapeutic dose was determined all untoward symptoms disappeared, with one exception in which it was not certain that the treatment was regularly followed Of the eighteen patients six were slightly improved, five definitely better, and in seven the improvement was very marked, the patients returning to work after several months of invalidism some having even been bedridden In the slightly improved cases some relaxation of the rigidity occurred, but was insufficient to increase the practical efficiency of the patients The mental improvement was very striking in a number of patients, and Hohman urges that mental change ought to be considered a fundamental part of the disease

Anaesthetics

385 General Anaesthesia with Acetylene Gas

T BRANDT (*Norsk Mag f Laegevidenskaben*, August 1924 p 669) is much impressed by the value, as a general anaesthetic, of pure acetylene gas, which is very different from the gas of a carbide lamp Since Wieland and Gauss published their investigations in February, 1923 in the *Klinische Wochenschrift*, several large hospitals in Germany have tested this new anaesthetic and have found it to be satisfactory from many points of view It is given with oxygen in various concentrations, and the apparatus is therefore rather complicated The patient rapidly loses consciousness without that preliminary respiratory inhibition which is often so distressing with ether and chloroform anaesthesia There is seldom any excitation, and anaesthesia is complete in one to two minutes, though it may take five minutes for the muscles to relax fully Indeed, muscular relaxation may not be complete, and for this reason it may sometimes be necessary to resort to ether or chloroform for laparotomies Brandt states that the patient can be kept under the anaesthetic for hours with impunity, and that there is no risk of overdose, because even in the highest concentrations the gas seems incapable of paralysing the respiratory centre When the operation is completed the mask is removed, and if the mixture of acetylene has been weak the patient recovers consciousness almost immediately, even when the mixture has been strong consciousness is recovered in two to five minutes The patient feels quite well, and headache and nausea are rare The disadvantages of acetylene anaesthesia are its rather high cost, the complexity of the apparatus, the inflammability of the gas, the absence of complete muscular relaxation in some cases, and the increase of blood pressure which is provoked and which contraindicates this gas for patients already suffering from this condition

386 The Dangers of Local Anaesthesia

L CHEINISSF (*Arch de med, cir y esp*, October 11th, 1924, p 49) alludes to the 43 deaths following the use of local anaesthetics which were investigated by the United States Council of Pharmacy and Chemistry A detailed study of the cases showed that in 40 of the 43 cases death was solely or mainly due to the local anaesthetic 24 of the cases were in males and 16 in females The youngest patient was aged 3 and the oldest 70 Twenty occurred in hospital, 10 in consulting rooms, 6 in dispensaries, and in the rest no details were given As regards the position of the patient at the time of administration of the anaesthetic 15 were lying down and 21 were in a sitting position about the others no statement was made Autopsies were performed in 20 cases, but did not show any lesions indicating individual susceptibility such as status lymphaticus Most of the deaths were due to cocaine employed in solutions of a strength ranging from 0 5 to 20 per cent especially after application to the throat for removal of tonsils In other cases cocaine was applied in the form of a paste in combination with adrenaline Many deaths were due to the use of strong solutions of cocaine associated with extremely large doses of adrenaline Intra urethral injections of cocaine proved particularly dangerous, especially in cases of trauma or stricture The following applications seemed to be harmless a solution of 5 per cent cocaine for conjunctival buccal and pharyngeal use, and a solution not exceeding 10 per cent for intranasal application and for the larynx and bronchi The rule should be that, whatever mode of application is employed, the dose of the local anaesthetic should be rigorously fixed, and preparations of unknown composition and concentration should be avoided Freshly prepared and sterilized solutions should always be used

387 Open Ether Administration

A OGSTON (*Brit Journ Anaesth*, October, 1924, p 76) describes a simple addition to the ordinary gauze covered mask for open ether administration which obviates the objections to prolonged induction and wastefulness The gauze retaining ring is replaced by a ring carrying wire uprights about four inches long and connected at their upper ends by another slightly wider ring After the mask has been covered with gauze and the retaining ring closed a folded towel is wound tightly round the upright frame so that it fits closely round the bottom, thus forming a cylinder having the gauze mask at the bottom and its wider opening uppermost Into this prepared mask, resting upon a pad of cotton wool with a hole in the centre large enough to uncover the nose and mouth, ether is dropped, at the rate of about one drop every two or three seconds, round the sides of the gauze avoiding the centre for the first minute, the rate of dropping being increased as rapidly as the patient can tolerate it continuous dropping to keep the gauze thoroughly wet being aimed at By this method ether otherwise wasted is utilized, and the expired ether vapour becomes available to augment the percentage of ether in the next inspiration The induction period can be reduced and made pleasanter by open nitrous oxide ether sequence if the tube from a nitrous oxide cylinder is held just inside the top of the mask until consciousness is lost, when the cautious administration of ether commences until automatic breathing is established The nitrous oxide is then cut off and the anaesthesia continued with ether alone

Obstetrics and Gynaecology

388 Primary Chorion epithelioma of the Ovary

D DOUGAL (*Brit Journ of Obstet and Gynaecol*, Autumn Number, 1924 p 387) gives details of nine cases of primary chorion epithelioma of the ovary described in the literature and adds a new case In the majority of cases the patients were young (under 31), all patients save one had been pregnant the last recognized gestation having usually preceded the operation by one to two years The symptoms were (1) abdominal pain, (2) irregular bleeding preceded in about half the cases by (3) a period of amenorrhoea Of ten cases seven were fatal the majority soon after operation, no patient survived the operation longer than two years In the author's case the second pregnancy terminated in a four months abortion nine months later there was abdominal pain accompanied by dark haemorrhagic discharge An abdominal swelling was now noted, together with amenorrhoea for the five months preceding operation The right ovary was considerably enlarged and contained numerous lutein cysts The soft enlarged uterus contained an intact decidua but was entirely free from growth The left Fallopian tube was normal save for flattening from pressure ovarian tissue was recognized both in the centre and periphery of the large chorion epitheliomatous growth on the right side The author has not found any record of other cases in which ovarian or broad ligament chorion epithelioma has been associated with the presence of a decidua in the uterus, but such a structure has been found there in cases of extra placental chorion epithelioma in the vagina in the myometrium and in the brain lung and kidney Dougal adds that the likeliest explanation of the occurrence of primary chorion epithelioma in the ovary is a preceding ovarian pregnancy

389 The Endometrium of the Menstruating Uterus

E NOVAK and F W TE LINDE (*Journ Amer Med Assoc* September 20th 1924 p 900) report twelve cases of removal of the uterus at some time during menstruation for either pelvic inflammatory disease or myoma In all these patients the menstrual rhythm had been perfectly normal and the menstrual dates were carefully checked Great care was taken to avoid injuring the endometrium during the operation As a result of their study of this material they are convinced that extensive loss of tissue is the rule during menstruation the entire superficial or compact layer as well as most of the deeper or spongy layer being thrown off On the first day the mucosal surface may be intact but more often it shows commencing loss of tissue by the second day the throwing off has become very extensive Rejuvenation changes are usually evident on the third day and may be quite marked The mucosal desquamation is preceded by

extensive infiltration with polymorphonuclear leucocytes and lymphocytes The mucosal throwing off does not usually occur as an extensive shedding in large masses, but is rather a kind of crumbling molecular process These results favour the modern conception of menstruation as consisting of a premenstrual hypertrophy of the endometrium in preparation for the impregnated ovum, together with an ensuing katabolic process to which the name "menstruation" is usually given when no fertilized ovum is present The authors add that there is much truth in the saying that "women menstruate because they do not conceive"

390 *Myomata in the Puerperium*

L W Tischmann (*Surg., Gynecol and Obstet*, September, 1924, p 227) agrees with Bland Sutton that the danger arising from gestation complicated by myomata, far from terminating with labour, extends well into the puerperium Post partum haemorrhage is fairly common, and, if due to intramural or sessile submucous growths which interfere with uniform retraction of the uterus, is usually early and often alarming Pedunculated submucous growths interfere less with retraction, but may be a cause of considerable haemorrhage at the time of their expulsion from one to five weeks after labour *Puerperal infection after gestation in the myomatous uterus* is relatively common, and is frequently due to the necessity for intervention As a rule uterine involution is retarded Inversion of the uterus is not uncommon, and usually accompanies an attempt of the organ to expel the myoma per vaginam Turning to the effect of the puerperium on the myoma, the author states that in the majority of cases the tumour diminishes considerably in size, but he casts doubt on the cases of complete disappearance of fibromyomata after delivery which have been recorded Exceptionally the tumours may increase in size after labour because of progressive fatty or myxomatous changes Abscess formation and gangrene are not very uncommon in myomata after pregnancy is over With respect to *treatment, it is advised* that when pregnancy in a myomatous uterus has continued to term, Caesarean section, with an immediate myomectomy or hystero-myomectomy, is the operation of choice, when the myoma is not discovered until during labour or in the puerperium, conservative measures should be practised as long as possible.

Pathology.

391 Phagocytosis and Cellular Reactions in Immunity

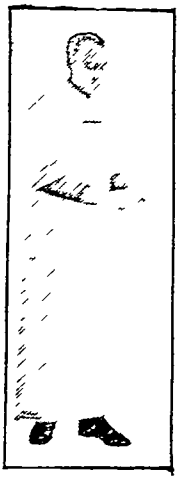
S Metalnikov (*Ann de l'Inst Pasteur*, September, 1924 p 787) reports some experiments on the processes of infection and immunity in caterpillars His general procedure was to inject a small quantity of emulsion into the body of the caterpillar, and, by making films of the blood during the subsequent hours, to determine the amount of phagocytosis which occurred Emulsions of various kinds were employed, mainly consisting of dyes or of bacteria The injection of dyes was followed rapidly by phagocytosis, so that in five to eight hours all the particles had been ingested and removed from the blood In the case of organisms the reaction which followed depended largely on the particular species injected and the dose in which it was given Generally speaking, it was found that the organisms which are pathogenic to man, such as the tubercle, plague, diphtheria, leprosy, tetanus, and anthrax bacilli, were comparatively harmless to the caterpillar, whereas the saprophytic organisms, such as *B subtilis* or *B anthracoides*, were highly pathogenic Exceptions occurred, however, as in the case of cholera vibrios and pneumococci Once ingested the bacilli were digested by the intracellular ferments of the phagocytes If a very large number of bacilli were given, the leucocytes frequently collected around them, fusing into plasmodia, in this way digestion seemed to be more easily accomplished In the case of tubercle bacilli giant cells were formed, sometimes actual capsules appeared completely enclosing the bacilli, which then gave rise to a process of caseous degeneration The phagocytes seemed to find little difficulty in dissolving these organisms, within a few hours the majority of them were taken up by leucocytes and lysed If the "cold blooded" type of tubercle bacillus was used the result depended on the temperature at which the caterpillars were kept after injection When they were maintained at 15 to 18 C phagocytosis was very active, but intracellular digestion was in abeyance, in consequence, the bacilli multiplied within the leucocytes, ruptured them, and gave rise to a fatal infection When, however they were kept at 37 C not only was phagocytosis very active, but intracellular digestion proceeded apace so that the organisms were completely destroyed It has been held by many workers that phagocytosis is inversely proportional in degree to the virulence of the organism, the author does not agree with this as he finds that many highly virulent bacteria which give rise to rapidly fatal disease are often ingested with eagerness He considers rather that virulence must be regarded, *not* as a cause affecting phagocytosis, but as proceeding from it It is the organisms which for some reason or other the leucocytes will not attack that prove virulent He comes to the reasoned conclusion that phagocytosis must be regarded as the most important defence of the individual, the part played by antibodies is merely an accessory one, confined to the higher animals He is thus a strong advocate of the present French school which is teaching the importance of cellular immunity

392 Production of Antibodies by Cutaneous Immunization

A Gratia (*C R Soc de Biologie*, October 7th, 1924, p 709) brings forward evidence which throws a considerable amount of doubt on the accuracy of Besredka's conclusions with regard to the mechanism of the production of immunity to anthrax by the cutaneous method of inoculation Besredka found that he was able to protect guinea pigs against the injection of virulent anthrax bacilli by vaccinating them previously by the cutaneous route, this was of particular interest because vaccination by other routes, such as the subcutaneous, proved ineffective Failing to find antibodies in the blood of animals which had received the cutaneous vaccination, he came to the conclusion that the skin was the only organ in the body which was susceptible to anthrax, and that by rendering it insusceptible to infection by this organism, the whole body was protected Gratia has repeated Besredka's experiments, and finds that though his facts are partly correct, his explanation is very doubtful He states that the assertion that guinea pigs can be protected by cutaneous inoculation is *perfectly true*, but the report that there is no antibody formation in response to this procedure *is unfounded* In the serums of these animals Gratia has been able to demonstrate the presence of agglutinins even in a *dilution of* 1 in 10,000 Moreover, the existence of protective bodies can be demonstrated by mixing the serum of the animal (vaccinated cutaneously) with anthrax bacilli, leaving the mixture for half an hour, and then injecting it into normal guinea pigs The animals remain perfectly well, whereas those injected with a mixture of *normal* serum and anthrax bacilli succumb It is therefore clear that antibodies are formed in response to cutaneous vaccination, and that they cannot be excluded from consideration when accounting for the immunity produced in this way The author thinks that the most likely interpretation is that, when the bacilli are injected into the skin, they are able to multiply and to give off their toxic products, to these the animal reacts by forming immune bodies, particularly anti aggressins, which confer a high degree of immunity upon it On the other hand, when the bacilli are introduced subcutaneously, they are taken up by the leucocytes before they have had time to liberate their aggressins, and the response of the animal is therefore less *strong* In a paper with Bernice Rhodes (Ibid., p 797) Gratia shows that the cutaneous vaccination of guinea pigs with cholera vibrios likewise gives rise to immune bodies, which can be demonstrated by the production of passive immunity in normal animals injected with the blood of animals vaccinated by this route Similarly, by vaccinating rabbits cutaneously against chicken red cells, they were able to demonstrate the appearance of haemolysins in the blood From all these experiments it is concluded that the hypothesis of local immunity put forward by Besredka is not in agreement with observed *fact*

393 Digestibility of Fresh and Sour Milk

Orla Jensen and B Spur (*Ugeskrift for Laeger*, September 4th, 1924, p 655) give an account of tests they have recently conducted on fresh and sour cow's milk They state that since cow's milk possesses a very considerable "buffer" action, it is obvious that the more sour it is the more easily will it be digested by pepsin The point is of considerable importance for persons whose gastric juice is deficient in hydrochloric acid The authors, being under the impression that accurate investigations have not hitherto been made in this field, have studied the rate of artificial digestion with a constant strength of pepsin (0·2 per cent.) and varying degrees of acidity The cow's milk was, [illegible] and kept at blood temperature in a thermostat in which artificial digestion was promoted by constant movement absolutely uniform parallelism could be established between the hydrogen ion concentration of the milk and the rate of dissolved to undissolved nitrogenous matter from time to time It would therefore seem possible that it is not the hydrogen ion concentration of the milk, but also the specific character of the acid radicals, which influences the rate of digestion But, as the authors anticipated, they found that acidified milk was more easily digested than milk



Miller

SURGEONS' APRONS.

Full length pure gum rubber surgeons' protective aprons, with large bib, neckstraps, and waist band

No metal clips or fabric used in their make-up, save fabric insertion to strengthen the neck and waist-bands

LEADERSHIP

THE prestige that has been won by leadership is maintained and shall we say, enhanced by the introduction of a new Calcott—the 12-24 h.p. It is a car eminently designed for those who respond to excellence. All who have seen this car admit that it has a marked smoothness in action, a flow of power and riding comfort that only comes from a well-bred car displaying in its conduct the heritage of a long line of ancestors. A remarkably fine car moderately priced. No mass production effort but a car designed right and built with the care of a craftsman. A car with qualities that preserve leadership—a car just a little ahead of its time. Three Seater £365. Four Seater £375. 4/5-Seater Saloon, £525.

The new 10-15 Calcott for 1925 has been re-designed, enlarged and improved to such an extent as to immediately place it above the average light car class. In power, roominess, comfort, and completeness of equipment it is equal to many cars of higher rating and cost. De Luxe Two-Seater Semi-Coupé £270. De Luxe Four Seater £270. Popular Two-Seater £255. *Dunlop Balloon Tyres standard to all models. A post card will bring a handsome illustrated Catalogue free of cost from* CALCOTT BROS. LTD. COVENTRY.

X RAYS for General Practice

¶ X RAYS offer a most important addition to a General Practitioner's service, the value of which it is impossible to compute.

The 'General Practice' X-RAY APPARATUS

is the latest production of the Medical Supply Association Automatically safe guarding against those scientific and technical difficulties previously met by the inexperienced it is expressly prepared for the service of the General Practitioner, and by its means he is enabled to produce valuable radiograms with ease and efficiency

"You switch on, we do the rest."

Price Complete

For Alternating Current £185 0 0

„ Continuous „ £230 0 0

Extra for latest modification to enable the X Ray Tube to be used from beneath the couch upwards as well as from above the couch downwards thereby making the apparatus universal in its application Extra **£18 10 0**

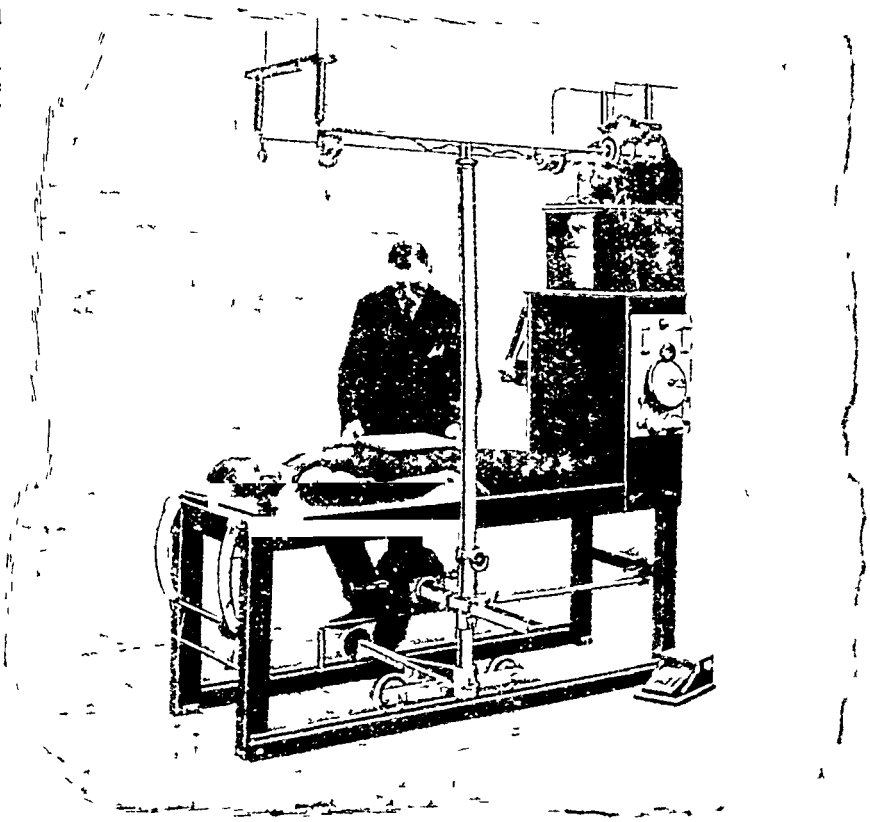
NOTE —The above price is for the complete installation inclusive of accessories viz —

High Tension Transformer Filament Heating Transformer Filament Control Coolidge X Ray Tube Oil Cabinet for supporting apparatus Radiological couch vertical screening stand marble switchboard x ray tube stand for radio therapy and dental radiography Foot switch for remote control fluorescent screen with protective lead glass front intensifying screens intensifying screen cassette photographic tank development outfit dark room photographic lamp radiographic compressor Anti Corona high tension overhead conductors illuminated negative viewing box PATENTED TECHNIQUE DIRECTOR FOR INDICATING THE IDEAL FACTORS FOR RADIOGRAPHING ANY PART OF THE HUMAN BODY WHICH ENABLES ANYONE TO USE THE APPARATUS EVEN THOUGH THEY HAVE HAD NO PREVIOUS EXPERIENCE IN RADIOGRAPHY

mean Accuracy of Diagnosis as well as Increased Remuneration

¶ There is no substitute for the X Rays.

¶ A scientific and congenial service with a good remuneration



¶ RADIOGRAPHY BY THE NEW "Technique Director" process is now so simple that any Doctor can use it

¶ *Call and see the apparatus at work Continuous daily demonstration, or send for Catalogue No 22 B fully descriptive*

"I enclose cheque in settlement of my account I have adjusted the rails for trolley as you suggested and they are to entirely satisfactory

The high quality of the radiograms I am obtaining exceeds my highest expectations, and I can unhesitatingly recommend the apparatus to any surgeon who has to, or prefers to do his own X Ray work —Yours faithfully,

"——— M D M S Lond F R C S Eng

Virol Scholarship in Haematology

The Directors of VIROL LTD offer a scholarship of the annual value of £200 for the encouragement of British research in Haematology

Candidates must be of British birth and either be registered Medical Practitioners or hold approved scientific degrees They must have taken up the study of pathology physiology or clinical medicine at a recognized Medical School or Laboratory in Great Britain and must if elected, undertake approved research in Haematology

For this purpose the award is restricted to a study of the histology embryology or pathology of the blood corpuscles and haemopoietic organs Serological bacteriological, biochemical, or clinical investigations will be accepted only when necessary to elucidate or supplement the above

The scholarship will be tenable for one year and renewable for a second year at the discretion of the examiners

In awarding the scholarship regard will be held by the examiners to the following points —

(*a*) Original work published or intended for publication by the candidate, or

(*b*) Evidence of ability and opportunity to *pursue original research in Haematology*

(*c*) The previous record of the candidate before and after graduation Evidence submitted under (*b*) and (*c*) must be attested by not more than three testimonials given specially for this purpose

Selected candidates may be examined orally and practically on their knowledge of haematology

The examiners are —

SIR WILLIAM WILLCOX KCIE, CB, CMG, MD, FRCP
ALFRED EINEY, MD, MRCP
A KNYVETT GORDON, MB

Applications should be sent to Dr KNYVETT GORDON 10 Bedford Square London W C 1 by December 1st 1924, marked "Virol Scholarship in Haematology" and must be typewritten They should cover the points mentioned above, and evidence of the permission of the director of the institution where the candidate is at present working for his or her entry for the scholarship must be supplied Original testimonials should not be sent in the first instance

The holder of the scholarship will be required to begin research early in January 1925

The candidate will be expected to publish results of the research in a recognized scientific journal

Royal Society.

GOVERNMENT GRANT FOR SCIENTIFIC INVESTIGATIONS

Applications for the year 1925 must be received at the offices of the Royal Society not later than January 1st next and must be made on printed forms to be obtained from the Clerk, to the Government Grant Committee, Royal Society, Burlington House, London, W 1

United for Service

"Poor Helpless Man"

He is not so helpless as the ladies think His bachelor den has a fascinating air of comfort about it He swears by and not at his fire—it's gas, his hot bath is a joy to revel in, thanks to gas And as a cook, well, "even a man can cook by gas"

Bachelor comfort is gas comfort

THE INITIAL TREATMENT OF DISEASE

FROM times immemorial it has been common medical practice to begin the treatment of acute infective invasion with a measure of depuration Experience has confirmed the wisdom of this course, but it is not, perhaps, so generally recognized that a similar practice is no less desirable with many chronic disorders Not only is clogged physiological machinery unable efficiently to carry out its ordinary work, but it is much less responsive to any specific remedial measures that may be applied

In order to bring about that cleansing of the tissues which should be preliminary to all specific therapy, a very simple routine is generally adequate Repeated experiment has shown that an initial fast of from twenty-four to seventy-two hours, broken only by the free drinking of water and the taking, twice or three times daily, of a spoonful of ENO's ' Fruit Salt," increases manifold the prospects of relief or cure Fasting alone is found to lead to abnormal fermentation of the intestinal contents Hence the necessity of supplementing the fast by moderate doses of such a substance as ENO's "Fruit Salt," which brings about efficient elimination with the minimum of functional disturbance.

The Proprietors of ENO s 'Fruit Salt will deem it a privilege to send any member of the Medical Profession for his personal use a bottle (Handy or Household size as desired) of their preparation with a copy of

' THE PRACTITIONER'S POCKET BOOK

This little volume embodies in a concise form many practical axioms of interest and use to the practitioner numerous legal points of great importance to every doctor and the essentials of the chief procedures involved in general practice pathology Bound in morocco limp

THE EMULSION FOR CHILDREN

In many of the wasting diseases of childhood, a sensitive, irritable stomach and intestines preclude proper nourishment Under the administration of Angier's Emulsion these organs become pacified and retentive, digestion is strengthened, and the assimilation of food is normal and complete It is oftentimes surprising how quickly pale, flabby, weakly infants and children gain flesh, strength, and vitality when they are given the Emulsion systematically

We confidently urge its trial in marasmus, scrofulosis, inherited tuberculosis, anæmia, and in the malnutrition associated with acute infectious disease It is likewise one of the most useful and dependable remedies for the treatment of bronchitis, whooping-cough, and the respiratory affections associated with measles and scarlet fever The pleasant cream-like flavour of Angier's Emulsion and its ready miscibility with milk or water, make it eminently suitable for administration to children They almost invariably like it

Members of the BRITISH MEDICAL ASSOCIATION

are strongly urged

NOT

to accept any offers of assurance or insurance policies made in skilfully worded circulars without previously consulting the

Medical Insurance Agency,

c/o The British Medical Association, 429, Strand.

It is easier to offer complete financial protection than to give it, and easier to talk about financial strength than to attain or retain it Many policies are offered to Medical Men which are not at all suitable for them

The Medical Insurance Agency was formed solely to protect the interests of individual Medical Men in assurance and insurance matters, and to support the Medical Charities Its advice is free, expert, and impartial

You should assure your life and health, and insure your staff, your house, and household goods, and your motor car, but—you should do all these with Companies approved and recommended by the Medical Insurance Agency

THE MEDICAL INSURANCE AGENCY,

c o BRITISH MEDICAL ASSOCIATION 429 STRAND LONDON W C 2

THE M I A EXISTS TO PROTECT YOUR INTERESTS AND SAVE YOUR MONEY

EPILEPSY

Doctors have proved the value of

AMBRIODIN

In cases where other treatment has failed It quickly reduces the attacks without the undesirable effects which invariably accompany the administration of Potassium Bromide

A Doctor's Report, states — In the two cases locally the following have been the results A youth of 19 21 who had been under treatment at the local general hospital for many months with little or no benefit Various remedies had been tried by the honorary physicians He was having three or four fits a week I started with one tablet three times daily gradually increasing to two tablets three times daily His fits gradually decreased in frequency and strength and finally when he moved away he was only getting a very mild attack every five or six weeks The second case A girl of 17 18 Fits since she was quite young She too had been under treatment at local hospital with same remedies little or no benefit Since she has been taking these tablets her fits are much less frequent and not so strong

Trufood is standardised as regards each constituent and contains an unvarying 26 % of butter fat.

There is a mass of clinical evidence to prove that Trufood is a satisfactory substitute for human milk.

Scientific equivalent for human milk

Humanized Trufood is made at the Creameries Wrenbury from the purest milk that comes from the rich pastures of the Cheshire dairy country As the accompanying analysis shows it approximates very closely to human milk This result has been achieved by removing a part of the casein of full cream Cheshire milk so that after adding pure cream and lactose a humanized milk powder of the following composition results —

	Breast Milk	*Cow's Milk*	*Humanised Trufood*
Lactose	6 5	4.7	6 5
Fat	3 3	3 5	3 45
Casein	0 9	3 0	0.90
Lactalbumen	0 4	0 3	0 60
Salts	0 2	0.3	0 65
Water	88 7	87 7	88 5
	100 0	100 0	100 0

No other baby food on the market can make a higher claim

ENZYMES AND VITAMINS — The maximum temperature of the Trufood process is 145°F at which enzyme activity is not destroyed as it is in the roller method of drying The presence of the ferments of breast milk—amylase reductase peroxydase—can be readily demonstated In this Trufood is unique among milk foods All the evidence shows that it can be used invariably to replace human milk when hand feeding is required

Samples adequate for full clinical trial together with descriptive literature will be sent post free on request

As a Medical Man

You will agree, we think, that it is more to your professional interest to **know why**—

MILKAL
THE CLEAN MILK

is so good a baby food, than merely to **hear** that it is so

Milkal is made in Devon at a Model Creamery under the constant supervision of inspectors and chemists

MILKAL is produced by a special process of drying rich cows milk by spraying it into a current of air heated to a certain temperature and by cleansing it of pathogenic organisms without making it sterile Complete sterilization as you know has effects upon milk which are more undesirable than the few harmless bacteria remaining in the finished product The ratio of the constituents of Milkal is that of the solids of rich cows milk

The chief advantages of Milkal are —

100% soluble in water

The fat in the milk thus obtained does not rise to the surface as an oily mass

Practically no coagulation of the Albumen

The Calcium Casein balance is undisturbed

MILKAL LTD

VACCINE TREATMENT FOR TUBERCULOSIS

Detoxicated Tubercle Bacillus Vaccine is prepared from virulent strains of Tubercle Bacilli. The germs are subjected to mechanical disintegration in the presence of weak alkali which acts as a solvent of the liberated bacterial protoplasm. The waxy or "fatty" portion, forming an insoluble residue, is completely separated by filtration through Berkefeld filters and is discarded, consequently this preparation is a

"DEFATTED" VACCINE

as well as a Detoxicated Vaccine

(See BRITISH MEDICAL JOURNAL, *7th July, 1923)*

A large quantity of this Vaccine is now available.

Please address all enquiries to the

(D.V. Dept.) Genatosan, Limited,

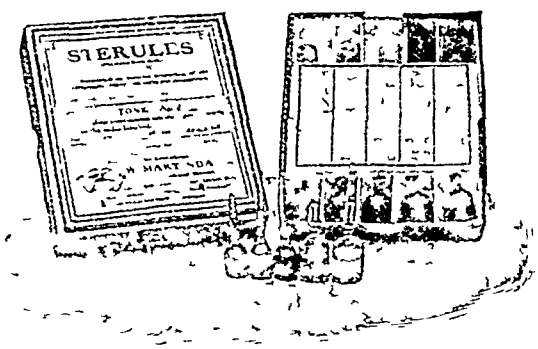
The Management of an Infant's Diet

Mellin's Food

contains 58 88 per cent of Maltose and 20 69 per cent of Dextrins



A proportion of Maltose and Dextrins best suited to the Carbohydrate needs of the average baby.

Mellin's Food

contains 10 35 per cent of Cereal Protein and 4 30 per cent of Salts which consist mainly of Potassium Salts, Phosphatic Salts, and a small amount of Iron

These facts should be considered in selecting a modifier of milk for infant feeding, for these facts indicate some of the reasons for the success of MELLIN'S FOOD which probably is unparalleled since the beginning of the study of the scientific feeding of infants

Samples, etc., free to members of the medical profession from

Extra Fats for Children's Diet

When a young patient who needs an extra allowance of fat during the winter months cannot tolerate oil emulsions, "Skippers" packed in Olive Oil will be found an invaluable alternative. They are small, delicately-flavoured Norwegian fish which appeal at once to the palate and are easily digested Children eat them readily either whole or mashed up with the olive oil and spread on bread

Only the purest olive oil is used for "Skippers," and the little silver fish themselves are rich in phosphates, so that a food of considerable nutritive value is presented.

Clinical experience indicates that Skippers are a most suitable form of food for diabetic patients, the oil helping to counteract the dryness of most diabetic foods

"Skippers"

FREE FROM HARD SCALES OR BONES

SKIPPERS in Oil or Tomato are guaranteed to contain no preservatives

The name ANGUS WATSON on any ready-to-serve food means the best of its kind

ANGUS WATSON & CO., LIMITED, ELLISON HOUSE, NEWCASTLE UPON TYNE

COLLOSOL ARGENTUM

(CROOKES).

A non-toxic, non-irritating, and stainless antiseptic.

CHIEF INDICATIONS.

Dermatology Its antiseptic powers towards lower organisms without injuring delicate tissues give it obvious advantages in all skin affections

Ear, Nose, and Throat Conditions In nasal and laryngeal inflammation and all catarrhal conditions the drug has given marked satisfaction

Ophthalmic Cases The outstanding advantages of Collosol Argentum are recognized by ophthalmic surgeons to whom its effectiveness and freedom from even slightly irritant properties makes a great appeal For prophylaxis against ophthalmia neonatorum it is already in use by some sixty County and Local Medical Officers of Health for the midwives under their control

Genito-urinary The non-irritant properties of the drug for the highly sensitive mucous membranes of the genito-urinary passages are fully realized

Bronchitis and other Throat Affections are amenable to this treatment

BRONCHITIS, Quinsy, Pharyngitis, Laryngitis, Influenza and other kindred affections of the bronchi, tonsils, larynx and throat are very quickly relieved by generous applications over the throat and upper thorax of hot Antiphlogistine

Antiphlogistine has a treble beneficial action

It reduces the inflammation and congestion, first from the fact that its generous c p Glycerine content coming in contact with the liquid exudates present, sets up and sustains heat, thus stimulating the cutaneous reflexes and greatly increasing local superficial circulation

Secondly, through the hygroscopic properties of Antiphlogistine, these same exudates, are, by osmotic action, actually taken into the poultice itself.

Its third beneficial action comes simultaneously with its first and second, and is its *endosmotic* action (the completment of osmosis)—during which its non toxic antiseptics of eucalyptus, boric acid and gaultheria are being taken through the integument, and, being absorbed, tend to inhibit the toxins.

Over 100,000 Physicians use the the genuine Antiphlogistine because they know they can rely on it to relieve inflammation and congestion

Let us send you our booklet, "The Pneumonic Lung."

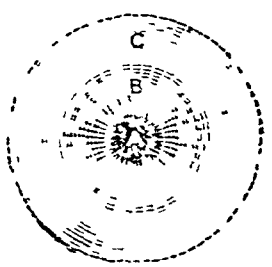
Antiphlogistine
TRADE MARK
"Promotes Osmosis"



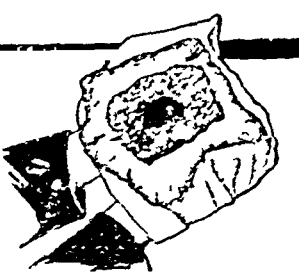


Diagram represents inflamed area. In zone C blood is flowing freely through underlying vessels This forms a current away from the Antiphlogistine whose liquid contents, therefore follow the line of least resistance and enter the circulation through the physical process of endosmosis In zone A there is stasis no current tending to overcome Antiphlogistine's hygroscopic property The line of least resistance for the liquid exudate is therefore in the direction of the Antiphlogistine In obedience to the same law exosmosis is going on in this zone, and the excess of moisture is thus accounted for

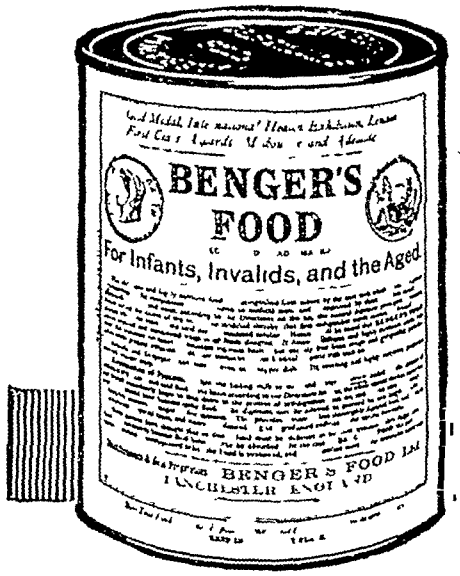
Antiphlogistine poultice after application. Center moist. Periphery virtually dry

Roboleine

completely solves the problem of supplying nourishment to delicate people of all ages, and to convalescents This statement is amply confirmed by the experience of the hundreds of doctors who have prescribed 'Roboleine' with success for many years It is significant also that 'Roboleine' should receive such praise as is contained in a letter from the Governor of the London Hospital, viz "The effect on some of our anæmic and rickety children has been magical"

FORMULA

Marrow from the long bones, Red Marrow from the rib bones of prime oxen, 'Cream of Malt,' Egg Yolk, and Neutralized Lemon Juice



CONSTITUENTS

Animal Fats, Maltose, Diastase, and natural Nitrogenous and Phosphoric Compounds

The undoubted Clinical results obtained by 'Roboleine' are due to the fact that the body-building elements constitute nourishment without overburdening or clogging the system

The "LANCET" describes it as "Mr. Benger's admirable preparation."

BENGER'S FOOD—the *adjustable* diet.

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing, the process being capable of arrestment at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes.)

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's Food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

The Ambulatory Treatment of Fractures and Diseased Joints,

By CAREL A. HOEFFTCKE

7, Harley Street, London, W 1

More than twenty years have elapsed since I first introduced the Ambulatory treatment for acute and chronic disease of joints, and for fractures of the long bones of the lower extremity

As is the case with many revolutionary changes in medical and surgical procedures, this treatment has met with a varied reception, but the numerous and favourable reviews of my book, in home and foreign medical papers, which have appeared, show that the principle involved in the Ambulatory treatment, namely, extension combined with movement, has found great favour with the medical profession

The difference between, and the advantage of, the Ambulatory treatment over the recumbent, must be apparent in cases of neck of femur fracture in elderly people as it obviates the danger of congestion of the lung, when the patients are enabled to assume an upright position and walk about within a week of the accident

When the patient is in the upright position, the circulation is not impaired, which therefore allows callous to form and union to be obtained more rapidly than if the patient has to lie in bed

In cases of tubercular and arthritic disease of the joints, the patients can be allowed to walk about and exercise the joints, which avoids slowing of the blood supply, and enables the usual blood current to combat the disease, and repair the articulating surfaces

The Ambulatory Extension treatment has upset the accepted opinion that nothing can be done to arrest the progress of the disease in cases of rheumatoid arthritis or even to prevent consequent deformity contractures, ankylosed joints, etc Hopeless cripples, who have been unable to walk for years, have not only obtained moveable joints, but also have been enabled to have the free use of their limbs without any evidence of the disease remaining

RHEUMATICS

By an eminent Physician

"Gentlemen—The subject you have chosen for discussion is one which, though of *the greatest* importance, happens to be, at the moment, very obscure and difficult

" Thus one finds as one blunders about in this swamp of 'Rheumatics' that each stone you try to step upon tilts you up and plays you false

" Lastly, there is one method upon which I would like to say a few words, though I must deal with it cautiously There are cases of severe arthritis in which the disease has become quiescent, but in which, either owing to the initial severity, or from lack of knowledge, or the character of the patient, severe contractures have resulted one or both knees, for example, have become fixed at a right angle and the patient has been unable to walk, possibly for years These are sometimes dealt with by forcible extension and elaborate splints—a treatment associated with the name of Mr Hoefftcke . .

" This, however, I must say, that in three out of four cases, all of the worst type, in which I followed through the results, they were eventually remarkable The fourth case, a hip joint affected with osteo-arthritis, was a failure, but I am not prepared to alter my mental attitude because this was a failure, for the cases I am dealing with are most difficult, and there must be failures I can only repeat that I have seen three remarkable successes When I am faced by a patient with contractures of long standing, unable to walk or earn his living, I ask myself What method other than this is open to use? . "

RHEUMATICS

By Carel A Hoefftcke

" . . The danger of injury does no doubt exist if the wrenching is done without extension or Under such conditions the joint surfaces are pressed together by strong muscular tension, and as the surfaces are usually eroded there is serious danger of injury If, however, the joint surfaces are kept separated while the manipulation takes place this danger is avoided Such separation can only be obtained satisfactorily by an extension table or extension splint Futher, the suffering which the patient has to bear is in a large measure due to the contact of the diseased joint surfaces and is, accordingly, greatly reduced by suitable extension Cases treated by my ambulatory extension method in arthritic or tubercular disease need not be quiescent, in fact, the earlier the extension treatment is applied the sooner a good result can be expected "

"The Lancet," *January 5th, 1924* review —

" And it should be stated clearly that he works only with the medical profession and [illegible] or who offers a substitute for medical services . . . "

The Lloyd Roberts Lecture

ON

THE RENAISSANCE OF MIDWIFERY

BY

HERBERT R SPENCER, M D, B S LOND, F R C P,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL

[DR HERBERT SPENCER began by saying that the Medical Society was perhaps influenced in its choice of a lecturer this year by the facts that he enjoyed Lloyd Roberts's intimate friendship during the last twenty-five years of his life, that they were fellow workers in the same field of medicine and that the same subjects, especially old books, interested them both By way of commemorating the founder of these lectures, Dr Herbert Spencer then gave some particulars of David Lloyd Roberts's personality character, and habits from his own experience, and some particulars of the earliest books on midwifery in which he was especially interested and of which he bequeathed to the Royal College of Physicians such an unexampled collection Those books, published in the vernacular, were widely used for study by midwives and might be said to have started the Renaissance of Midwifery In collecting old books Dr Lloyd Roberts employed the most celebrated of the old book sellers, and, as he had more regard to the condition and rarity of the book than to the price, he was able to accumulate a very valuable library, especially of old medical books, which to the number of 1 800 (including 50 *incunabula*) he bequeathed to the Royal College of Physicians This was said by the Harveian Librarian, Dr Arnold Chaplin to be *the greatest gift of medical books to the College since the* Marquis of Dorchester's in 1680 He loved Sir Thomas Browne above all writers edited a charming edition of the *Religio Medici* learned Italian in his old age that he might read Dante (on whose scientific work he wrote a book) and his collections showed that he was a lover of the good and beautiful in men ideas and things After remarking that it was for his medical library that Lloyd Roberts would be longest remembered and especially for his unequalled collection of early medical books, including *The Byrth of Mankynde* (1540), Dr Herbert Spencer continued]

It is the purpose of this lecture to give some particulars of the first books on midwifery in Germany, France Italy, and England, which may be said to have started the renaissance of midwifery

Obstetrics is an ancient art It was outside the Garden of Eden that midwifery was born " of man's first disobedience," with the dread decree to woman " in sorrow thou shalt bring forth children " And we find the Garden of Eden incident referred to and depicted in some of the first books of midwifery

The early history of midwifery is too extensive to be treated here, but it may be stated that the most distinguished of the ancient writers on obstetrics was Soranus of Ephesus who lived in Rome at the beginning of the second century of the Christian Era under Trajan and Hadrian He wrote *περι γυναικειων παθων* which stands out as one of the most important works in the history of midwifery which had at that time reached a high state of development

Subsequently the art of midwifery made no advance at the hands of the Byzantines, and actually declined amongst the Arabians, who devoted more attention to the destructive operations on the child than to conservative treatment of the mother One factor in preventing advance in the science of obstetrics amongst the Arabians was the prohibition of anatomical research in the Koran But the chief reason why no advance was made was that the practice of midwifery was in the hands of midwives as it had been since the earliest times Up to the time of the Renaissance no midwife had written a work which developed the science or advanced the art or dignity of her calling

Until the invention of printing the wisdom of the ancients was inscribed in manuscripts comparatively few in number usually written in the classical languages and therefore readable only by the learned For the preservation of these works we are indebted in great part to the various religious bodies and especially to the monks The Church of Rome which has at times opposed the pursuit of medical knowledge, has also been one of its greatest promoters Many examples of this are given in Curatulo's *L'Arte di Juno Lucina in Roma* And there are not a few instances of ecclesiastical dignitaries who have been practitioners of medicine Pope John XXI the only member of the profession to occupy the papal chair was a doctor who taught medicine in Siena in the middle of the thirteenth century As Petrus Hispanus he published his work *The aurea Pauperum*, which was printed for the first time in 1470 In the Lloyd Roberts Collection at the Royal College of Physicians are three copies of the work including one of the 1494 edition Nicholas de Fernham an Englishman, was professor of medicine at Bologna whence he returned to England in 1241 and became Bishop of Durham

The renaissance of midwifery occurred somewhat later than that of other branches of learning The intellectual world was in labour, in the throes of delivery from the domination of the Church, from the blind acceptance of the authority of the ancient writers Aristotle and Galen and from the restrictions of the classical languages The Reformation had brought about the first stage Paracelsus did something to bring about the second stage when he cast the works of Galen into a bonfire in the streets of Berne and anathematized his opponents with the words "sic vos ardebitis in Gehenna" and Eucharius Rösslin seized the opportunity afforded by the discovery of printing to publish his *Rosengarten* in German so that it could be understood by the people and particularly by the midwives for whom it was written Although Ortolff von Baverland had published, about the year 1495, at Ulm a German work showing " how women should conduct themselves before during, and after childbirth " it did not contain much detailed account of obstetrics To Rösslin is due the honour of the first printed work specially written for midwives

RÖSSLIN'S 'ROSENGARTEN'

Eucharius Rösslin (Rösslin or Rhodion) was a physician at Worms and afterwards at Frankfort-on-the Main According to documents still existing at Freiburg in Breisgau Rösslin was an apothecary there in 1493 and 1493 In 1504 a legal action was brought against him for "mishandling" as the result of which a verdict was given against him and he was compelled to pay all costs and a fine of 3½ pounds of pfennigs In 1506 he was elected physician to the city of Frankfort for a period of six years at a yearly stipend of 60 florins In 1508 he entered the service of the Duchess of Brunswick and Lüneburg to whom he dedicated his *Rosengarten* Before the expiry of his term of office he left (in 1511) Frankfort and became city physician to the town of Worms returning again to his Frankfort post at an increased salary of 70 florins According to Baas he died in September 1526

V Siebold in his *Geschichte der Geburtshülfe* (1845) makes a curious error in giving the date of his death as 1553 or 1554 confusing this Eucharius Rösslin with his son, who bore the same name and died in 1553 or 1554 The error is the more remarkable because in the Latin translation of the *Rosengarten* entitled *De partu hominis* there is a preface dated 1532 written by Christian Egenolph and addressed to Eucharius Rhodion which refers to the death of the father " cui bene sit in Domino cuju[s] hac urbe tu et nomen refers et functionem " In this work Rösslin acknowledges his indebtedness to the ancient writers Hippocrates, Galen, Rhazes Averroes Avicenna and Albertus magnus but the most important parts are taken from Soranus probably from a manuscript by Moschion (or Mustio) which itself was copied from Soranus word for word "

It is suggested by Gustav Klein that Rösslin edited the *Codex Palatinus Latinus* which was at that time in Heidelberg not far from Freiburg Worms and Frankfort where Rösslin lived Some of these manuscripts dating from the ninth to the fifteenth century were illustrated among the most interesting being the plates of the foetus *in utero*

Abstract of the second Lloyd Roberts Lecture delivered under the conjoint scheme of the Royal College of Physicians the Medical Society of London and the Royal Society of Medicine at the Medical Society of London on November 19th 1924

which, reproduced in the English translation, *The Byrth of Mankynde* (1540), were among the earliest copperplates published in this country. The figures have been often reproduced. One plate, not met with in the earliest manuscripts, shows twins grasping each other by the heel, thus was probably drawn by a monk in reference to the birth of Jacob and Esau. Rosslin also published some admirable original plates—namely, the dedication plate depicting the author presenting his work to the Duchess of Brunswick and Luneberg, a plate showing the midwife examining a parturient woman (Fig. 1), and a figure of the birth-chair.

It is stated by G. Klein that about a hundred editions of *Rosengarten* are known, three editions being published in 1513. He gives a reproduction of the title-page of the 1513 edition, printed by Grau at Hagenau, which shows a mother with her naked boy and a midwife holding a babe wrapped in swaddling clothes. The title-page of the 1524 edition is also given by G. Klein. It is a fine representation of the lying-in chamber, showing the midwife bathing the baby. The midwife sits with her bare legs in the tub, no doubt to make sure that the water was of a proper temperature—a useful practice adopted also by the Japanese midwives.

FIG. 1.—From a copy of the 1513 edition in the Library of the Royal Society of Medicine.

Under the title *De partu hominis* Rosslin's son published a Latin translation, of which, according to Klein, eleven or twelve editions appeared, the first in 1532. The title-page of my copy of the 1554 edition gives the representation of the lying-in chamber reversed from that in the *Rosengarten* 1524 edition, and some quaint woodcuts, depicting the feeding and tending of the child.

The *Rosengarten* was translated into English by Jonas under the title *The Byrth of Mankynde*, and published for the first time in 1540. A second amended English translation was made by T. Raynalde, who used the Latin edition of E. Rhodion the younger. The late Dr. J. W. Ballantyne wrote a very full account of the English work, giving illustrations from many of the editions. He had not had an opportunity of inspecting the first edition, which is very rare, the only three copies he had been able to find in existence being in the libraries of Professor Klein of Munich and the British Museum. The Royal College of Physicians now possesses fifteen copies (eleven editions) of *The Byrth of Mankynde*, of which eleven copies, including two of the rare first edition, came from the Lloyd Roberts collection. The celebrated plates of the position of the foetus appear in this edition, and not for the first time in the 1566 edition, as once stated by Dr. Ballantyne.

The *Rosengarten* contained little that was original, but it had the merit of being written in the vernacular, in which it could be read by midwives, in whose hands the practice of midwifery almost entirely lay. It was the first work dealing with obstetrics apart from medicine and surgery, and in its illustrations it gave for the first time printed figure of the birth-chair, the lying-in chamber, the position of the foetus at term, and of the feeding and tending of the child, as well as the first printed figure of the placenta. Of high interest and importance, also, were the woodcuts, including Rueff's and Ambroise Paré's.

Ambroise Paré's Obstetric Works.

The first of the obstetric treatises by Ambroise Paré entitled "La maniere de extraire les enfans tant vivans hors le ventre de la mere, lors que nature de soy peult venir à son effect" appeared at the end of his *Briefe collection anatomique*, published in 1551. His second treatise, "De la Generation de l'Homme tant des meres et modernes," was published as in octavo volume in 1573 under the title *Deux livres de chirurgie*, and was reproduced in 1575 in the first edition of the complete works of Paré.

In his "Maniere de extraire les enfans" Paré revived the operation of podalic version, which had been entirely neglected for many centuries. The operation had been practised in the time of Celsus, Soranus, and Philumena, but had found no place in the treatises of the Arabian physicians. Paré himself does not claim originality, but acknowledges that he had copied podalic version practised by Thierry de Hery and Nicolas Lambert, "master barbers and surgeons in this town of Paris." He also advises that the abdomen should be moderately bound and pressed down, the umbilicus, and the mother should be commanded to hold her breath at intervals by closing her nose and mouth, and that she should bear down as much as possible. Sternutatories may be given to aid in the expulsion of the child. He warns against pulling on the arms in presentation of the shoulder, for which he recommended, in certain neglected cases, amputation of the limb followed by podalic version.

Paré's reintroduction of podalic version after many centuries of neglect marks him as the master writer of the obstetric renaissance. His work was plagiarised by Franco in 1561, and attempts have been made in modern times to deprive Paré of credit by quoting from certain editions of his work. His obstetrics passed through many editions, and it was his practice to make alterations when additions to his knowledge called for them.

The work on *The Generation of Man* contains the anatomical and other figures, including the birth-chair, copied from Rosslin and Rueff. Paré published a figure of the caps for ulcerated nipples, which are still employed at the present day. I have in my library a work by T. Du Laurens (1565) with an autograph inscription by the author to Conrad Gesner, which recommends the application of cups or thimbles containing a few drops of pure wine to the nipples, to be worn during the last three months of pregnancy as a certain means of preventing cracked nipples. In criticism that some women or their husbands might object to the smell of the resin, Dunus replies that any such objection suffered from the *magnum malum*, cracked nipples, could tolerate the smearing not only of the nipples but of the whole breasts with medicines however obnoxious to the are examples, or such there are many, of the modern maternity cares by the Renaissance surgeons and also by Ortolan and Bouchacourt. He gives details of measurements of the foetus at term and of the movements of the child felt on palpation of the abdomen, described by Paré. He published a number of

instruments for the delivery of the dead child, and gave an illustration of the speculum matricis, an ancient instrument known to the Romans, also of instruments for the fumigation of the uterus. Of Caesarean section on the living he had seen disastrous results at the hands of Guillemeau, which caused him to write, "Je ne conseillerai jamais de faire tel œuvre ou il y a si grand peril sans nul espoir." It was in reply to this statement that his friend Rousset wrote the first work on Caesarean section *Hysterotomotokie* (1581).

The literature of the life and works of Paré is very extensive. As was the case with the founder of this lecture, there seems to be a doubt about the actual date of Paré's birth, the years 1509, 1510, 1514, 1516, 1517, 1528, having been given by various authors. Malgaigne states on the authority of Begin that "A. Paré was actually born in 1517." He would thus be 73, and not 80, as usually stated, at the date of his death. On St. Bartholomew's Day, 1572, "it was not reasonable that he should be massacred." King Charles IX. exclaimed after taking a shot with his arquebus at his less distinguished subjects, "il pouvait servir à tout un petit monde." This service Paré, the Reformer of Surgery, the Reformer of Midwifery, continued to render up to the time of his death in 1590—and his soul is marching on."

Scipione Mercurio's 'La Comare'

The first of the Italian writers for midwives was Scipione Mercurio who published his work entitled *La Comare o Ricoglitrice* in 1596. Scipione Mercurio was born in Rome about the year 1540. He studied medicine at Bologna and Padua, but soon devoted himself to theological studies and entered the Dominican monastery at Milan, where he took the name of Hieronymus. He still continued to occupy himself with the study of medicine, and finding his monastic life did not afford him sufficient opportunities for the practice of medicine he quitted the monastery and travelled in France and Spain in the years 1571 and 1572 as physician to a German officer, Hieronymus de Ladrone. On completing this journey he returned to Italy and practised with great success in Padua and Milan. He had studied in Bologna under the celebrated Arantius, of whom he speaks in the highest terms as "the most learned anatomist of his time and my very kind preceptor." He mentions a case in which he saw Arantius in the year 1578, deliver a living child by Caesarean section from a woman who had been killed in the ninth month of pregnancy. He states that Arantius had familiarized himself with the anatomical conditions of pregnancy by performing many dissections of gravid women. He had also seen Arantius demonstrate the hymen, the existence of which, except as a rarity, had been denied by Paré.

Scipione Mercurio states that in Toulouse he had seen two women who had been safely delivered by Caesarean section, which at that time (1571) was "as well known in France as bleeding for headache in Italy." He may be said to have introduced the operation of Caesarean section on the living woman into Italy, and published the first printed illustration of the operation.

Scipione Mercurio led a stormy and adventurous life, at one time travelling with a German officer, Ladrone in France and Spain, at another pursuing his theological studies, then abandoning these for the practice of medicine and again resuming them, finally settling in Venice, where he lived for fifteen years. He died about the year 1615 or 1616 according to Ghilini in Venice, according to Penazzi in Rome in the ancient Dominican convent of Santa Maria. His other writings show his great interest in medicine and he seems to have specialized in the practice of obstetrics. He had little faith in medical writers who lacked practical experience. If they did not like his work, let them do him the great favour of not reading it. Perhaps the less it pleased his critics the more it would please others. He acknowledged that he had profited by the works of others—he gives a list of 80 authors whom he had consulted—and says he could never pardon Aristotle for adopting the statements of Hippocrates without once mentioning his name. Any errors in the work he prays the Lord will enable him to see and amend, and begs his critics not to censure that which is written for a good purpose. Mercurio's writings show that he was a man of wide erudition, which he was wont to bring to bear upon his critics in pointed shafts of wit and learning.

FIG. 2.—Title page of the second and third edition. The first of the first edition was published in the Journal of October 21st 1921.

La Comare is the first work in which contraction or the pelvis is mentioned as an indication for Caesarean section. It contains a description and illustration of the "hanging-legs" position for delivery in cases of contracted pelvis which Walcher published in 1889 as something new, and of the position in which very fat women should be placed for delivery—a position which Osiander says even practised acrobats could hardly maintain for more than a quarter of an hour. There is also a description of the operation of bimanual version which is usually associated with the name of Braxton Hicks. Mercurio advised that the diet of pregnant women should be reduced one-third during the last three month.

The work is divided into three books. The first book deals with natural labour and the care of the pregnant woman and of the newborn child by the midwife. The

second book deals with preternatural labour (that is, with the child's hands, feet, or side presenting), and shows how the midwife should deal with these "difficult and dangerous cases." The third book deals with the maladies which may occur to the lying-in woman and newborn child, and teaches the midwife how to treat these maladies in case the patients do not wish or are ashamed to call in a doctor.

Von Siebold, in his *Geschichte der Geburtshulfe* (1845), says *La Comare* was first published at the beginning of the seventeenth century—Haller gives the date of the first edition (which he had not seen) as 1604. Quetif and Echard, the biographers of Mercurio, speak of an edition which appeared before 1600, but leave the matter doubtful.

The first edition actually was published in 1596, the second and third books being dated 1595. That *La Comare* is a *cinque cento* book was first made known by Davidson of Breslau in 1864. A few years ago I was fortunate enough to obtain a copy of this edition, which is very rare, only three other copies being known to exist. Fasbender says there were seventeen editions of the work, and Curatulo gives a short account of these seventeen editions. I possess two editions (1680 and 1686) not mentioned by Curatulo, and these, with the 1713 edition in the Lloyd Roberts collection of the Royal College of Physicians, bring the number of the editions of *La Comare* up to twenty.

The first edition, *La Comare o Ricoglitrice*, Venice, G. B. Ciotti, 1596 (second and third book dated 1595), quarto, is very rare. There is a copy in the Marciana Library at Venice, another in the library of the Arcispedale in Florence, a third in the Alessandrine Library at Rome, and a fourth copy is in my possession. There are some good anatomical figures from copperplates by Franciscus Valgrisius. The other figures are rough woodcuts. I have given a reproduction of the title-page and some other figures from this edition in the Harveian Oration (1921).[1]

The second edition, *La Commare o Ricoglitrice*, Venice, 1601, G. B. Ciotti, is also rare. The second book has no separate title-page. The third book is dated 1600. There is a remarkable title-page (Fig. 2) to this edition, which is dedicated to Octavian Malipiero, the stemma of whose family is given below, and above is a portrait of Catherino Malipiero, who fell while engaged in sinking the Turkish fleet at the battle of Lepanto (1571), in which Cervantes was wounded and lost the use of his left hand. At the sides of the title-page are figures of Scipio Africanus ("bellicæ gloriæ") and Cato of Utica ("reipublicæ splendori"). The artist is not named, but a comparison with his other work shows that the plate was engraved by Valgrisius.

The third edition appeared in 1606 (title-page is in second edition, dated G. B. Ciotti 1601). In his dedication (of the first book) to Octavian Malipiero the author signs himself Girolamo Mercurio Romano, "from the convent of S. Eustorgius at Milan, 30th October, 1604," and states that this is the third edition, "ristampata la terza volta" (reprinted for the third time), which really means *printed* for the third time, for he adds that he dedicates it to Malipiero with the same affection as he did the second impression ('la seconda impressione'). The second book has Ciotti's "Minerva" printer's plate and is dated 1606. The third book has similar title-page and date (1606) to the second. This edition is sometimes called the 1604 edition (for example, by Curatulo) and was thought by Hall to be the first edition. The title-page is that of the second edition, and, although the dedication is dated 1604, the dates on the title-pages of the second and third books show that it did not appear till 1606.

William Harvey's "De Generatione Animalium"

The renaissance of midwifery occurred later in England than in Germany, France, and Italy. It had made some progress as a result of the appearance of translations of the works of Rhodion and Paré, but no original book on the subject had been published until 1651, when Harvey published his *De Generatione Animalium* with the chapter "De Partu" which justifies Aveling's designation of Harvey as the Father of British Midwifery. I have elsewhere[2] given a detailed account of Harvey's contributions to embryology and midwifery, and have pointed out the teachers at Padua who had specially written on those subjects. Spach's third edition of the *Gynaecia*—a collection of ancient and recent writers on gynæcology—had appeared in 1597, and the first edition of *La Comare* had been published in 1596, four years before Harvey went to Padua to study. Scipione Mercurio had himself practised obstetrics at Padua, and it was probably the great attention devoted there to obstetrics and the appearance of *La Comare* (the second edition was being prepared when Harvey joined the university) which stimulated Harvey to emulate the Paduan obstetrician by writing his "De Partu," the first original English work on midwifery.

The *De Generatione Animalium* consists of seventy-two "exercitations," followed by chapters on "labour," "the membranes and humours of the uterus," and "the conception." The first (Latin) edition, printed in London, 1651, contains a striking title-page representing Jove sitting on a throne and opening an egg from which various animals are escaping; on the egg is printed "ex ovo omnia," a pregnant generalization which Harvey made as a result of his researches on generation. The legend is omitted from the egg in the first Amsterdam edition (Leers, 1651).

The first English edition appeared in 1653 with a portrait by Pelham, which is often missing. It is one of the best of the engraved portraits of Harvey.[3]

Prefixed to the first English edition is a laudatory ode to "the incomparable Harvey" signed M. LL. M.D., which stands for Martin Llewellyn, M.D. The English edition is written in quaint and spirited language and was probably produced under the supervision and with the approval of Harvey, who lived for four years after its appearance.

The great and original merit of Harvey's work on generation lies in the careful and methodical observation and record of the embryo and fœtus at all stages. Harvey did for development what the illustrious Paduan professor Morgagni subsequently did for disease in his *De sedibus et causis morborum* (1761). The chapter on labour ("De Partu") deals with the subject from a scientific and practical point of view. The scientific part consists in criticism of previous opinions on the anatomy and physiology of the fœtus and on parturition based on his own observations. The practical part gives evidence of extensive personal experience in midwifery, and is in the main devoted to the recommendation of patient watchfulness and gentleness, imitating Nature, in ordinary cases and podalic version in different ones.

England was not only the last of the great countries to produce a writer on midwifery, but was equally tardy in the recognition and regulation of its practitioners. In 1616, the year in which Harvey was propounding his immortal discovery of the circulation of the blood, Peter Chamberlen II. made a petition to King James that some order might be settled by the State for the instruction and civil government of midwives, but nearly three hundred years were to elapse before the desirable result was obtained in the Midwives Act (1902), through the persistent efforts of the Obstetrical Society of London. Harvey inveighs against the meddlesome officiousness of the midwives. Another distinguished obstetrician, his friend Peter du Willughby, writes more fully of their shortcomings and misdeeds, and testifies to the value of Harvey's teaching.

The first books on obstetric renaissance in Germany, France, Italy, and England achieved their object of being widely read by midwives, as we learn from the history of Louise Bourgeois and Justine Siegemundin. The books introduced them to the wisdom of the ancient writers, and, in the cases of Paré and Mercurio, to methods of treatment which had been long neglected and forgotten. England was fortunate in having, as the Father of English Midwifery, Harvey, who introduced into that branch of medicine the wide view, the scientific spirit, and the conservative practice which have been its characteristics. It was Harvey's inculcation of patience and gentleness in imitation of Nature, adopted by Smellie and Hunter, which made such a strong impression on Boer, the founder of the great

[3] The latest portrait is a "white line" wood engraving of the Canterbury portrait by Horace Gerrard, the first pull from this plate is in the library of the Medical Society of London.

Viennese school of midwifery, who, after studying in France and England, adopted the British practice 'having learnt in France what Art, in England what Nature, could do"

The purely British operation of induction of premature labour for cases of contracted pelvis can be attributed to the same conservative spirit And if we add the discovery of the foetal circulation by Harvey, of the forceps by Chamberlen of chloroform by Simpson, and of the antiseptic system by Lister, we may claim for British medicine that though it was last in producing a writer on obstetrics it has not been least in conferring benefits on parturient women

ENCEPHALITIS LETHARGICA

BY

E FARQUHAR BUZZARD, MD, FRCP,

PHYSICIAN, ST THOMAS'S HOSPITAL

WHEN I had the honour of addressing this society on the subject of lethargic or epidemic encephalitis in December 1918 our interest was aroused by the recent outbreak in our midst of a disease which we regarded as a stray visitor, whose sojourn might not unreasonably be expected to be of short duration, and whose back we should not be sorry to see Events have not justified this expectation as our guest is still outstaying his welcome and shows as little inclination to take his departure as we can show of ability to expedite it

At the end of six years his role has changed from that of a casual, unwelcome visitor to that of a resident pest providing a serious menace to the health of the community It is not to be wondered at that a disease which has so insidiously and so successfully established itself should present many points of interest for discussion It is somewhat humiliating to our professional pride that we have not only so far failed to check its progress but that we are still without the knowledge necessary to achieve that object Before 1918 the term 'encephalitis' was reserved almost entirely for an acute specific inflammation of the brain to which children or young adolescents were liable and of which the cause was the virus of poliomyelitis To-day the young and old of both sexes are exposed to the danger of contracting another inflammatory disease of the brain, sometimes acute, at other times subacute or chronic prolific in its clinical manifestations, disabling if not fatal in its results difficult to diagnose and almost defiant to treatment and prognosis It is true that its microbic origin seems to be fairly determined that its morbid anatomy has been studied in great detail and that its clinical features have formed the theme of innumerable papers and monographs, but of its path of approach, of its methods of dissemination, and of any weapon with which to stay its hand our ignorance is still profound

Remembering as we must, that the secrets of medicine are rarely divulged without the laborious study from all available standpoints of every feature of a disease which presents itself there is no need to be discouraged The more profound and the more detailed our knowledge of a disease in all its aspects the more likely are we to solve the mystery of its origin and the problem of its prevention

In opening this discussion to night I shall make no attempt to deal with all the problems presented by epidemic encephalitis which are of interest and which deserve consideration both from clinical and pathological points of view I shall content myself with directing attention to one or two questions which are difficult to answer and which have important practical bearing confident that those who follow me will more than make up for my omissions

So much has already been written in regard to the clinical manifestations of encephalitis in the acute stage that it is hardly necessary to point out that the disease has no real characteristics in the way of symptoms or physical signs by which it can be recognized Since any function of the brain may be disturbed it is obvious that a whole multitude of different symptoms and physical signs may be presented The diagnosis depends on a careful consideration of the history of onset the course of events and on the exclusion of other morbid processes which are capable of producing similar disturbances of function We are not in possession of any serum or other chemical test by which the disease can be detected and although examination of the cerebro-spinal fluid is often helpful in a negative way by eliminating other diseases it cannot be said to afford us a cytological or chemical picture which is entirely pathognomonic

Although there are so many difficulties in the diagnosis of the acute disease they do not present nearly so serious a problem as that involved in the detection of what may be called the ambulatory form or encephalitis And yet the importance of this ambulatory form in regard to its subsequent developments is becoming more and more impressed on our minds as time passes by We are constantly being confronted now with serious disorders of the central nervous system in patients whose history alone offers a clue to the origin of their troubles and in this way we are gaining some insight into the clinical features which characterize the ambulatory form of the disease

I could cite a number of examples in which serious and disabling disturbances of the nervous system have followed what appeared to be a very minor illness which has been regarded as influenza or even as an ordinary catarrh

In July of this year I was consulted by a man 37 years of age who in the latter part of 1919 suffered from a short illness characterized by slight fever headache and general pain insufficient to prevent him from carrying on his duties in the army In 1920 he pursued his ordinary life but complained that he was drowsy all day and restless at night and about that time began to suffer from attacks of dyspnœa which were of frequent occurrence during the next two years In August 1922 he first noticed some tremor of the right arm and a slight generalized rigidity which he described as preventing him from ever sitting at rest in comfort These symptoms slowly increased writing and shaving became difficult and he occasionally suffered from headaches of mild severity When I saw him in 1924 he was still working but suffered from a frequent desire to lie down and sleep and found the performance of his duties involved a great effort On examination he presented all the characteristic features of the post-encephalitic Parkinsonian syndrome

A somewhat similar case is that of a man of 53 who in December 1922 suffered from what was regarded as a bad cold which kept him away from work for a fortnight During that time he noticed that he was slow and shaky in his movements and inclined to bend forward in walking He returned to work at the end of fourteen days feeling queer but able to carry on for about three months when he developed an access of great loss of confidence out of doors with a tendency to fall backwards He rapidly became slower and more clumsy in his movements was hardly able to dress himself and failed to do himself justice in his work When I saw him in October 1923 he presented the appearance of a patient suffering from paralysis agitans as well as other disorders of cerebral function including a slight degree of memory aphasia and impairment of his capacity to recognize objects placed in his right hand with his eyes closed There was considerable exaggeration of all his tendon jerks and his plantar responses were extensor in type

In considering the history of these two patients it is difficult to see on what grounds a diagnosis of a serious disease of the central nervous system could have been made at the time when they were first taken ill They may perhaps be regarded as somewhat exceptional because in the majority of cases of ambulatory encephalitis it is possible to obtain a history of some symptom pointing very definitely to organic disease of the nervous system by far the most common being a transient diplopia which not infrequently is present only during a few hours or a few days

There are other symptoms which might well arouse a suspicion of encephalitis in patients suffering apparently from some minor ailment I may refer to the occurrence of an acute pain affecting a limb or perhaps the face or neck generally labelled as a neuralgia or a rheumatism of great severity but generally lasting a few hours four hours or at the most two or three days I have frequently observed such attacks of acute pain in cases of severe encephalitis in which the diagnosis has not been in doubt but they also occur sufficiently often in the ambulatory form of the disease to be worthy of note in relation to diagnosis

A paper read in opening a discussion at the Medical Society of London on November 10th.

A lad of 20 in the early part of this summer suffered from severe pain in his left arm and leg which lasted for twenty four hours and was associated with some slight malaise sufficient to keep him away from his employment for three days On returning to work at the end of that period he found himself inclined to sleep in the train while going to his job and was very sleepy while at work This drowsiness continued, and at the end of a fortnight he was troubled by diplopia for a period of forty eight hours During this time his relatives noticed that he was completely altered in temperament, having become depressed and morose and quite unlike himself He was inclined to be restless at night and to sleep in the afternoon When I saw him, at the end of ten weeks, he presented no definite physical signs of organic disease, but he was still quite unfit for any serious mental or physical exertion, being very easily tired and still much depressed I saw him again about three months later, when he still complained of insomnia at night and inability to walk more than a mile without fatigue Examination on this occasion revealed the presence of some lack of expression on the left side of the face, which gave rise in my mind to a strong suspicion that he was developing a Parkinsonian syndrome

While on the subject of the more obscure and slight forms of encephalitis attention should be directed to the great difficulty which may sometimes present itself in making a diagnosis between encephalitis and early disseminated sclerosis I cannot indicate this difficulty better than by recording an experience which I had in March, 1921, when there was a severe epidemic of encephalitis in London

I was asked to see a lady, aged 40, who gave me a history that about a month before I saw her she had noticed diplopia followed ten days later by a feeling of numbness over the left side of the face and by a suspicion of difficulty in articulation She thought that her memory had not been quite so good as usual, and she had suffered on several occasions from nocturnal enuresis For a few days she had been feeling rather unsteady on her legs On examination there was very slight right sided ptosis with some nystagmus on deviation of the eyes to the right side only Sensibility over the skin area supplied by her left fifth nerve was impaired, and she complained that she had lost her sense of taste There was very slight unsteadiness and awkwardness of her hands when her eyes were shut but she complained of no difficulty in ordinary manipulations The right abdominal reflex was less brisk than the left The right knee jerk was somewhat more brisk than the left and the right plantar response not so frankly flexor as that obtained in the other foot

It appeared to me that the clinical features presented by this patient could be attributed equally well to encephalitis or to disseminated sclerosis but in view of the prevailing epidemic I inclined somewhat to the former diagnosis I saw her again in July, 1921, when she expressed herself as being perfectly well, and my examination then revealed no disorder of the nervous system The ptosis nystagmus, and awkwardness of the hands had completely disappeared and her reflexes were perfectly normal This patient remained quite well until the summer of 1923, when she suddenly became unsteady on her legs, developed marked dysarthria with dimness of vision in her left eye She then presented nystagmus in both directions pallor of the left optic disc, weakness of the left side of the face and tremor of the right hand Her tendon jerks were increased the abdominal reflexes had disappeared, and the left plantar response was distinctly abnormal

I have no doubt that this patient is suffering from disseminated sclerosis, and the rapid improvement which took place in regard to these later symptoms was only in conformity with what one expects in that disease

I do not propose to take up your time with a description of the sequelae which have been so often observed after acute attacks of encephalitis, as these have been the subject already of many discussions and many papers, but there are one or two points in connexion with these late developments which deserve further consideration They have a most important bearing on the question of prognosis, and any information which can help to make prognosis easier is worthy of note

In the present state of our knowledge only a very courageous or very ignorant doctor would willingly assume the rôle of a prophet when faced with a case of acute encephalitis lethargica in the first week or two of the disease In such a position one is only justified in pointing out the various possibilities which the future holds for the patient, and these possibilities, which are numerous, may be briefly summarized in the following way

1 The patient may recover within a reasonable time and suffer from no subsequent ill effects

2 The patient may die in the acute stage of the disease

3 The patient may live, but remain permanently more or less disabled as the result of the disease

4 The patient may make an apparent recovery and yet relapse after a period which may vary from a few weeks to a few months, or perhaps even longer

5 The patient may make a more or less complete recovery, and yet after a variable interval develop one of the slowly progressive sequelae which are now well recognized as legacies of lethargic encephalitis

The position of the prophet is, therefore, obviously not an enviable one, and any attempt to make his task easier can at present be based only on insufficient and unreliable data Some comments are, however, perhaps justifiable in this connexion The more acute the onset and the more fulminant the outbreak of symptoms, especially when associated with high temperatures, the more serious is the outlook in regard to a speedy fatal termination Unfortunately it cannot be said that the milder initial stages are in any way exempt from the possibility of being followed by serious and permanent disablements of a progressive character, nor from the possibility of a complete recovery being followed by a more severe and possibly fatal relapse after a few weeks or months On the other hand, there is no doubt that many mild cases make good recoveries without further developments The difficulty of prognosis depends on the fact that we are without criteria which would enable us to pick out the more hopeful cases I cannot help thinking that a much longer experience of this disease is still necessary before we can arrive at reliable statistics in regard both to mortality and to permanent disability Personally I should be very sorry to attempt to reckon the probabilities in regard to the results of the disease in any kind of figures or percentages

One of the many interesting points worthy of discussion to-night is the question as to how far late developments can be regarded as true relapses, as merely indirect consequences of a morbid process which has ceased to be active, or, in rare cases, as examples of fresh infection I have in mind patients who appear to be examples of these three occurrences For instance, I recall a man about 50 years of age who, after a few days of ill health, suddenly passed into a state of unconsciousness, rapidly followed by a delirium which lasted for about seventy-two hours, and, recovering from this, he suffered for another week or two from severe headache, diplopia, and a certain amount of mental confusion A gradual convalescence set in which was rudely broken at the end of about three months by the onset of severe headache, hemianopia, and other active cerebral symptoms, which proved fatal in the course of about three weeks On the other hand, I have in mind the case of a lady whose initial illness in the winter of 1918-19 was characterized by slight pyrexia, diplopia, lethargy, and myoclonic movements, but who made, apparently, a complete recovery and remained in her normal condition for a period of five years At the end of that time she was again seized with diplopia, pyrexia, headache, and rapidly increasing clouding of consciousness, and died after an illness which only lasted three or four days The particular interest in this case lies in the fact that a thorough *post-mortem* examination was made, and that the evidence of old as well as recent inflammation was detected in the course of the microscopical examination of the brain tissues Attempts, however, made by Dr Greenfield to inoculate animals with the virus from this patient proved entirely unsuccessful We are left, therefore, quite unable to decide whether the fatal attack should be regarded as a long-delayed flare-up of the initial inflammatory process or whether it was the result of an entirely fresh infection in a patient whose acquired immunity, if there be such a condition in relation to this disease, had faded out It may be noted incidentally that the second attack occurred at a time when cases of encephalitis were extremely prevalent

While discussing the question of prognosis it may not be out of place to refer briefly to a question which is not infrequently put to us in regard to the duration of particular symptoms, and I should like to refer especially to the prospects of a patient who, after all other symptoms of the disease have disappeared, still suffers from myoclonic contractions In this connexion it is worthy of record that a medical man who suffered from an acute attack of

encephalitis in 1916, was still suffering from frequent bouts of myoclonic contractions in his trunk muscles when I examined him in 1920 When I last saw him a year ago the movements had nearly ceased, and only reappeared from time to time when he was overtired He was then, and still is, leading a very strenuous life in general practice and is in no way disabled I was consulted in regard to his qualification for a life insurance policy and expressed the opinion, which was accepted by the office that he might be taken on at ordinary rates This opinion was expressed as the result of my experience that the persistence of myoclonic contractions should not be regarded as an unfavourable symptom from the prognostic point of view I might even go further, and say that even in acute cases the presence of severe and widespread involuntary muscular contractions is not necessarily of grave omen

The sequelae of encephalitis are worthy of close study from an academic point of view on account of the light which they may help to throw on the localization of cerebral functions I do not propose to make any comments on the striking changes in temperament and behaviour which are well known to follow in the train of this disease, but I should like to draw your attention to some interesting phenomena which not infrequently are associated with the post-encephalitic Parkinsonian syndrome Only a few weeks ago I had the opportunity of discussing with an intelligent patient suffering from that condition the alterations which had taken place in what one might call her everyday experiences She complained that in addition to her general slowness of action she was still inclined to drowsiness and to attacks of uncontrollable yawning While she could detect no impairment of memory, nor of her ability to grasp subjects in which she was interested, she was much handicapped in her daily activities by attacks of what she called 'shortness of breath" which on further analysis she described as periods during which she had to breathe consciously She remarked that the same attention was necessary for deglutition and that she could only sip her tea because each mouthful had to be swallowed by a conscious effort, the actual process causing her some annoyance because of its noisiness She presented, what is so common in these patients, considerable impairment of the power to converge and accommodate, which prevented her from reading for any length of time In regard to her rigidity she explained that she could relax her muscles voluntarily, but as soon as she stopped thinking about it the muscles became screwed up again The reason why she liked to have massage was that she got *tired of the feeling of muscular tension and that rubbing* relieved it and served to some extent to prevent attacks of cramp She also described a curious habit which beset her when she was standing in the erect position Her weight was constantly being transferred alternately from one foot to the other unless she directed her attention to it So long as her attention remained fixed on the idea of standing still she was able to do so, but the moment her mind was distracted the movement of transferring her weight from one foot to another returned

The cases presenting the Parkinsonian syndrome appear to illustrate a pathological condition in which many functions purely automatic in normal health can no longer be aroused to activity except under the influence of the higher centres, and it is not surprising that patients suffering in this way find that the burdens and duties of life have been materially increased by their illness

We are accustomed to associate this Parkinsonian syndrome with lesions of the basal ganglia, and it has possibly struck some of us as being rather curious that with few exceptions the progressive sequelae of encephalitis take this form Is it not possible that there are other progressive sequelae of the disease occurring less commonly and perhaps not yet recognized? During the last three or four years I have been faced by a number of cases of progressive hemiplegia, generally starting with a disability of one limb, which spreads first of all to the other limb and face on the same side and then appears in the limbs of the opposite side finally producing the picture of a double hemiplegia In these cases the disability is mainly a motor one, but is not infrequently accompanied by slight sensory disturbances of cortical origin This condition has appeared in patients with no arterial changes and therefore could not be ascribed to a progressive defect in cerebral circulation The process has been associated with headache vomiting or optic neuritis, but the absence of any signs of increased intracranial pressure has not deterred me in one or two instances from advising an exploratory operation of the brain When this has been done no gross changes have been visible and I am beginning to suspect that the progressive disability may be the legacy of unrecognized encephalitis and characterizes a group of patients comparable to those presenting the Parkinsonian picture In the latter case the chief incidence of the disease is on the basal ganglia, and in the former a similar process may be operative on the cerebral cortex In a few of these cases I have noted the occurrence of an illness, regarded as influenza, preceding the onset of the symptoms referable to the central nervous system but I have not sufficient evidence at the present time to do more than suggest the explanation I have indicated as a possible solution of the problem they present

It may be that the advent of encephalitis in an epidemic form—and it is difficult to believe that it is a disease entirely new to us—may in the long run throw light on the etiology and pathogenesis of some obscure disorders of the brain notable for psychological and physical disabilities At any rate there is no need to apologize for having devoted much of your time and mine this evening to a study of the dire results which are apt to follow comparatively trivial disturbances of the nervous system The practical lesson to be learnt from our experience of the last few years is that no minor ailment involving definite evidence of organic nervous lesions, however slight, should be treated with anything but the greatest consideration It cannot be stated as a proved fact that with more rest and care in the early stages of mild encephalitis late serious developments may be prevented, but on general principles such an expectation is certainly permissible Inactivity is an essential part of the treatment which we employ for inflammation in any part of the body, no exception to this rule can be justified in the case of our most highly specialized, most delicate, and yet most valuable tissues

ANEURYSM OF A BRANCH OF THE RENAL ARTERY RUPTURE NEPHRECTOMY. RECOVERY

BY

R P ROWLANDS OBE, MS, FRCS,

SURGEON TO GUY'S HOSPITAL

SPONTANEOUS aneurysm of a branch of the renal artery as a source of symptomless haematuria is so exceedingly rare that the following case seems to be worth recording

A married lady aged 47 was brought to me by Dr Bower Jones of Carmarthen in December 1918 She had been suffering from very severe haematuria for three weeks and was getting rapidly worse in every way There was no history of recent injury or illness The bleeding had begun suddenly It was of a profuse and continuous that it was thought at first to come from the uterus later it became intermittent and clearly came from the bladder during micturition There was no history of renal pain or colic nor was there any palpable enlargement or tenderness of either kidney A complete x-ray examination failed to reveal any urinary calculus Cystoscopy was difficult owing to the large amount of blood clot in the bladder but ultimately it was proved that the blood came in large quantities from the left ureter and that normal urine issued from the right

As the patient was very ill and bloodless the left kidney was explored without delay through the usual oblique incision in the loin It was found to be enlarged adherent and deeply congested its pelvis was greatly distended with blood No stone could be felt in the latter nor in the kidney The pelvis was incised and bright red blood rushed out and a finger introduced failed to find any tone or other cause for the furious bleeding the nephrectomy was performed at once The patient made a good recovery but he took a long time to recover from the severe anaemia She has remained in good health and is well over six years later

Upon opening the kidney and its pelvis from end to end the streaks of altered blood and an infarct were seen in the renal substance, and a ruptured aneurysm the size of a

large pea, was found partly on the surface of one of the lower renal papillæ. It arose from one of the intrarenal branches of the renal artery. It is unfortunate that, owing to the pressure of military surgery, the specimen was not preserved.

Aneurysm of the renal artery is very rare. M. J. Conroy[1] estimated from *post-mortem* records that only about 1 per cent. of all aneurysms affect this artery. Sir Henry Morris,[2] in 1900, was able to collect the records of only 21 cases, and two-thirds of these were traumatic in origin. Conroy, in 1923, succeeded in adding 11 cases, but he overlooked 3 cases published by David Newman[3]—making 35 in all. Two of Newman's cases were very like the one recorded here, for they were spontaneous in origin, saccular, and situated within the kidney or its pelvis. One of these arose in the renal artery itself, and the other, like mine, originated in one of the large branches of this artery. It is clear that this type is not easily recognized even when the kidney has been exposed in order to find and stop a painless hæmaturia which threatens life. It is probable that small aneurysms affecting the branches of the renal artery have been overlooked even after the kidney has been removed, either during life or after death. It would have been easy to miss the small aneurysm which caused so much mischief in my patient.

Apart from hæmorrhage, these intrarenal aneurysms cause no symptoms or signs and are only found after death from some other disease.

Ætiology

We are not concerned here with traumatic aneurysms of the renal arteries, which are due to contusions, lacerations, rupture, wounds, or operations upon the kidney. The cause of *spontaneous aneurysms* is the same here as elsewhere. Atheroma, syphilis, embolism, or infection appear to have been the causes in the few recorded cases, in my case there was no evidence of any of these. The average age of the seventeen known cases of spontaneous aneurysm was over 40. A little more than half of them arose from *branches* of the renal artery.

Symptoms and Signs

Spontaneous aneurysms are usually small in size, remain intact and give no clinical signs, but when they rupture into the pelvis "symptomless hæmaturia," which is generally very profuse and either intermittent or remittent, occurs. This is in striking contrast to traumatic renal aneurysms the majority of which cause large tumours in the loin and much pain with or without hæmaturia.

Diagnosis

The diagnosis of spontaneous renal aneurysm depends chiefly on the great severity and recurrence of the painless hæmaturia, the absence of any history of injury, and the absence of the shadow of a renal calculus. It is interesting that in several cases (including my own) the bleeding was so severe that it ran continuously out of the urethra, so that its source was at first thought to be uterine. Several cases have needed a catheter because clots blocked the urethra. Cystoscopy, after washing out the bladder, proves the absence of vesical growth, and the issue of blood from one ureter indicates that the source is in the corresponding kidney. Newman, in two cases, noticed what he regards as a diagnostic sign—that is, "when interrupted pressure was made with the kidney between the hands—one behind and another in front—every time pressure was made a quantity of blood was seen to flow into the bladder, and when the pressure was withdrawn the flow ceased. This is found in no other condition." This sign, in his opinion, should distinguish renal aneurysm from all other causes of severe hæmaturia.

In my case the blood escaped continuously and with great force during the cystoscopic examination. I have not noticed such forcible and profuse bleeding even with renal neoplasm, which, by the way, often forms a palpable renal tumour—which spontaneous aneurysm rarely does.

Treatment

Without operation the prognosis of bleeding renal aneurysm, either traumatic or spontaneous, is very grave. An early operation offers the only reasonable chance of recovery. Hitherto nephrectomy has been adopted in all but one of the successful cases. Orth,[4] operating for traumatic aneurysm, turned out the clots and successfully sutured the tear in the renal artery, but as a rule the condition of the kidney in these traumatic cases is so bad that nephrectomy is necessary. Before removing the kidney it is necessary to prove the presence and activity of the opposite one.

So far the diagnosis of spontaneous aneurysms in the kidney has been so uncertain and incomplete that in the few recorded cases nephrectomy has always been adopted, and on the whole very successfully. With the aid of a pedicle clamp after delivering the kidney, incising the pelvis should enable us to make an accurate diagnosis of an aneurysm in a branch of the renal artery, and to remove the aneurysm, which is usually quite small, without any loss of blood. It would be a great advance to save the kidney in this way, but it is probable that in some cases the aneurysm may not be discovered, and possible that, in a few, another small aneurysm may be present in the kidney or subsequently develop in diseased arteries to give recurrence of bleeding.

Whatever operation is performed, these patients are usually so ill and anæmic that blood transfusion must be done in order to give them the best chance of recovery.

A PLEA FOR THE EARLIER OPERATIVE TREATMENT OF ACUTE OTITIS MEDIA

BY

F. HOLT DIGGLE, O.B.E., F.R.C.S.,

HONORARY SURGEON IN CHARGE OF EAR, NOSE AND THROAT DEPARTMENT, INCOATS HOSPITAL, MANCHESTER; ASSISTANT HONORARY SURGEON, MANCHESTER EAR HOSPITAL

There is, in my opinion, no branch of surgery more neglected than the treatment of acute otitis media. Almost every day one meets with cases where an acute inflammatory condition of the middle ear has been allowed to progress until a state of chronic suppuration, with all its attendant sequelæ, has resulted. Probably many factors contribute to this unfortunate result, but chief amongst them are, first, the ignorance of the general public, secondly, the lack, until quite recently, of compulsory training with examination of the medical student in the diseases of the ear, and lastly, the fact that, except in a few cases, a visiting otologist is not recognized as a necessary member of the staff of a large fever hospital.

The exanthemata are responsible for the majority of the worse types of suppurative middle-ear disease, and it is at their inception that so much can be done to prevent a progressive and chronic disease. It is to be hoped, therefore, that in the near future local authorities will see the wisdom of following the example set forth by a few of our large fever hospitals in appointing visiting otologists.

Given a case of acute otitis media, how should it be treated? All are agreed upon the value of an early incision of the tympanic membrane, and yet I wonder how often it is advised, judging from the large number of "running ears" where no such treatment was adopted. The ear is syringed, hot applications applied, and the appearance of pus in the meatus anxiously awaited. It is too frequently thought that when pus appears all is well, but Nature's perforation of the tympanic membrane is in practically every case a tension rupture—that is to say, the increased intratympanic pressure, from the accumulation of inflammatory products, is ultimately relieved by a bursting of the membrane.

The tympanic membrane is capable of withstanding a high degree of pressure, and in many cases, before the membrane ruptures, the increased intratympanic pressure has disseminated the infection into the posterior end of the middle-ear cleft—the mastoid antrum. Moreover, the perforation is small, usually on the summit of what was a bulging part of the membrane, and

therefore frequently most disadvantageously placed for the efficient drainage of the tympanum By early paracentesis efficient drainage can be established, the risk of spread of infection to the mastoid antrum materially lessened, and, in the vast majority of cases, pain immediately relieved It is an operation devoid of risks in the hands of those accustomed to aural surgery, can be performed under short anaesthesia, and gives excellent results both as regards preservation of hearing and resolution of infection

In the majority of cases so treated there is rapid cessation of the discharge which often is only serous, and the middle ear is generally dry at the end of ten to fourteen days, if not earlier In a few cases, however, this excellent result is not obtained, and in spite of timely paracentesis the ear continues to discharge profusely Two factors contribute to this result—namely the extreme virulence of the infection, particularly the type of organism and the presence of some meatal obstruction hindering drainage Infections due to the streptococcus or influenza bacillus are very prone to spread to the mastoid antrum Further, in some cases, perhaps by reason of the virulence of the infection, there is marked inflammatory swelling of the external auditory meatus This if occurring in a meatus congenitally narrow, considerably hinders efficient drainage of the middle ear

It is commonly believed that the only necessity for any operative treatment is when pain, tenderness on pressure or swelling behind the ear develops The development of such signs and symptoms may almost be regarded as a godsend, for then the case is efficiently treated and convalescence with cessation of discharge assured

The anatomical structure of the mastoid process decides whether pain, tenderness etc appear early or not They are evidences that the inflammation has spread so far as to involve the mastoid periosteum In the cellular type of mastoid process they frequently become manifest early, but in the acellular dense or sclerotic type they may be considerably delayed if they ever develop

There are, however, other earlier signs of involvement of the mastoid antrum—namely bulging and redness of the postero-superior part of the tympanic membrane and the adjacent portion of the posterior wall of the external auditory canal To appreciate this sign however requires some special training I would therefore urge that the persistence of suppuration after ten to fourteen days in spite of early paracentesis especially if associated with some inflammatory stenosis of the meatus is, even in the absence of pain, tenderness, or swelling an indication that something more than local medication is required and that the mastoid antrum should be opened, disinfected and drained

If such a procedure be not adopted the case may pursue one of two courses either the condition gradually progresses until the mastoid antrum and process is involved, demanding immediate operation, or there is gradual resolution of the discharge during several weeks until finally the patient declares that the ear is dry and he is quite well In some such cases we find that the perforation has healed and the membrane is intact, but permanent damage may have been wrought The membrane is frequently scarred opaque thickened, indrawn, and adherent to the inner wall of the tympanum, permanently impairing audition if not also producing other distressing symptoms such as tinnitus and vertigo In other cases, though the membrane may appear to be normal in texture and position, the hearing is defective, owing to adhesions around the ossicular chain or thickening with fibrosis of the muco-periosteum around the labyrinthine windows These changes are the result of long-continued inflammation causing excessive cellular exudation into the muco-periosteum, with ultimate fibrosis and sclerosis, and are permanent, no treatment being of any avail This class of case swells the out patient clinic and is distressing to see, particularly in view of the fact that so little can now be done, whereas so much was possible at an earlier date

Lastly it may be discovered that the perforation has not healed is still moist, although the patient on interrogation is quite convinced of the absence of any discharge This class of case often has remarkably good hearing, but he is the patient who frequently first seeks advice because of the sudden onset of some intracranial complication

If we wait until there are external evidences that the mastoid process is involved before resorting to operative treatment—a delay which may extend over a few weeks—then the pathological changes above described ultimately ensue, with some permanent impaired audition

Early Drainage of the Mastoid Antrum

By early drainage of the mastoid antrum I do not mean the so-called radical mastoid operation in which the tympanum, aditus, and antrum are thrown into one cavity, but the simple operation of exposing the mastoid antrum, curettage of its walls, disinfection of the interior with bipp, and primary suture of the incision

In 1921 I reported jointly with Mr Gilhespy the results of a series of cases so treated The average duration of stay in hospital after operation was twelve days At the end of this period there was no otorrhoea except in one case which was an acute exacerbation of a chronic suppuration necessitating a radical mastoid operation These cases examined one year or more after treatment showed an intact membrane with normal hearing Such results as these are shared by many and only go to prove the good results obtained by early operative treatment

I have frequently resorted to early exploration of the mastoid antrum in cases of persistent discharge with no gross lesion of the mastoid, and have had no reason to regret it It is an operation almost devoid of risk and followed by speedy healing and convalescence since the introduction of bipp it gives gratifying results both as regards cessation of discharge and preservation of hearing

There is in my opinion no greater field for the fulfilment of the principles of preventive medicine than in the treatment of acute otitis media—once deafness is established no known treatment is of any avail

Professor C H Browning, M D, President

MULE SPINNERS' CANCER AND MINERAL OILS

BY

ARCHIBALD LEITCH, M D,

Director of the Cancer Hospital Research Institute London

No less than 20 per cent of the fatal cases of cancer of the scrotum in this country occur amongst cotton spinners

By courtesy of the Registrar General for England and Wales we have had access to unpublished records which disclose the fact that during the two years 1913-14 90 men died from scrotal cancer and of these, 18 (or 20 per cent) were cotton spinners in the years 1921 22 the total number was 107, of whom 26 (or 24 per cent) were spinners and in 1923 there were 15 fatal cases in this industrial class This gives an average of 11 8 per annum No other group or occupations with the exception of chimney sweeps showed more than three cases Cancer of the scrotum is now a very common disease it is much less common in the general population than cancer of the penis for example During the first two periods mentioned there were 254 and 224 cases respectively of penile cancer, but not one occurred in cotton-spinners

Here, then we have something of practical importance, industrially and medically that calls for explanation and investigation—a particular form of cancer occurring in a certain industry—and yet, strange to say no one has within the last two years seemed to have known or to have suspected this association The consideration of this important discovery will be given to Southam and W Lond I our

mortality statistics, which are probably the best in the world, had been arranged so as to show localizations of cancers in relation to occupations, the liability of cotton-spinners to develop epithelioma of the scrotum would have been appreciated many years ago.

According to the 1921 census, 57,069 persons were engaged in cotton-spinning processes, including piecers and mule-, ring-, and flyer-spinners. As the piecers are almost without exception boys or very young men, and as female labour is employed exclusively in ring and flyer spinning, there remain only the mule-spinners to consider. Of these there are at the present time 23,000, all adult males. (It is believed that a few women, perhaps not more than a score or two, act as mule-spinners.) Thus, taking a yearly average of 11·8 cases, we find that approximately 1 in 2,000 mule-spinners die each year from cancer of the scrotum. This is startling enough, but if we assume that the carcinogenic agent implicated produces its effect only after many years of exposure to it, the elderly workers must have a greater liability still. What are the factors responsible for this affection?

Southam and Wilson, in examining the records of cases of cancer of the scrotum admitted to the Manchester Royal Infirmary for a period of twenty years, noticed that, out of a total of 141, 69 were mule-spinners, and they were led to investigate the conditions under which the spinners work. At present there is a lawsuit about the matter* and there is a conflict of opinion on certain points, which will be mentioned later, but the main facts are clear. Each spinner attends to a pair of machines, called mules, a portion of which—the carriage—advances and retires bearing on it the spindles on which the spun cotton is wound. Immediately in front of these rows of revolving spindles is a long horizontal steel bar—the counter faller shaft—2 feet 9 inches from the ground, which travels with the carriage. When the yarn breaks the spinner leans over this bar and pieces the ends. The frictional parts of the mule are lubricated by a mineral oil. The atmosphere in this department is kept warm and moist for technical reasons and the men perspire freely. The workers are lightly clad in a shirt and linen trousers, or in overalls, which are washed usually once a week. Southam and Wilson stated that the men's garments showed "a well-marked oil zone six to eight inches in depth across the body at the level of the upper part of the thighs and the lower abdomen. This oil penetrates the trousers and the lower border of the shirt also becomes soaked with it." This soiling they considered, was due to contact with the counter faller shaft which was covered with oil thrown on to it from the revolving spindles. On the other hand it has been stated that in some mills at any rate the shaft is free of all oil and the workers' clothes even at the end of the week show no such oil zone. I have had an opportunity of seeing a mule-spinning machine in operation, and though I could not detect any oil on the shaft on running my hand over it, yet I could not help noticing a deep oil smear in the left groin of the attendant of which he himself was unaware. It is possible that in the latest type of machinery the lubricated portion of the spindles is better guarded than in older types. Let us note in passing that the men's arms are exposed to the lubricating oil but they do not develop epithelioma in that situation. "The continual soiling of the clothes with oil," say Southam and Wilson, "and the knowledge that in other forms of cancer tar and paraffin are recognized as direct etiological agents—a view which has received considerable support from experimental work on animals—suggests that the oil, which has a highly irritant action on the tissues of the skin, may be of considerable importance."

What evidence have we that mineral oils have carcinogenic properties? In my original communication,[2] to which Southam and Wilson presumably refer, I gave the clinical and the experimentally ascertained evidence on the subject. Actually less than 20 cases all told of what is called "paraffin cancer" had been recorded in medical literature. Some of these had occurred in the shale oil works of Scotland, some in the lignite distilleries of the Halle district in Germany, and only two were reported from paraffin refineries in the United States of America. Later search has revealed in account by H. Ehrlich[3] of five cases in Czecho-Slovakia, and one case by Ullmann[4] in Galicia, but the latter states in a footnote that on circularizing medical men practising in the neighbourhood of oil fields in Galicia, Silesia, and Hungary, he learned that 25 cases were known to have occurred. Finally, Scott mentions that during a period of twenty-two years there were 65 cases of paraffin cancer amongst the workmen in the Scottish shale refineries. In all the known instances, with the exception of some of Scott's cases, the patients had been engaged for many years in handling the very crude products containing the more solid paraffins—that is, the fractions of high boiling points—and the scrotum was the part of the body most commonly affected. Scott, however, found that several cases of cancer of the scrotum had occurred amongst workmen who were not employed at the paraffin presses but dealt with subsequent processes, and it is possible that the scrotal epithelioma which they developed was due to constant soiling of the parts with the more refined commercial oils. No case of paraffin cancer has been reported from Germany for the last thirty-eight years, a fact which Kennaway[5] has attributed to some radical change in the methods of distillation or to the adoption of effective preventive measures by the workmen. The rarity of reported cases in America is remarkable. It is probably due to the fact that the unskilled labourers there do not remain long at one occupation, though it cannot be denied that industrial medicine has lagged behind in that country. On the whole, therefore, the clinical evidence that *refined* mineral oils are capable of producing cancer is weak.

In my previous experiments I stated that I had produced tumours in 30 out of 75 mice to which various oils of the shale group had been applied, the tumours being papillomata, epitheliomata, and even sarcomata. One of the products employed was a lubricating oil, classified as "unfinished," and with it we succeeded in *producing* a true epithelioma. The fact that such a *refined oil had* carcinogenic properties led us to inquire if skin cancers were at all prevalent in occupations entailing soiling of the clothes with oil, but no information could be obtained on the point. It was considered advisable to work through the whole series of the liquid products of shale distillation to see if the noxious property was retained in the more refined oils or eliminated in the course of preparation of the commercial products. It was rumoured that, though petroleum oils were usually employed for lubrication of machinery in the mills of Lancashire, yet, owing to the uncertainty of supplies during the war they had to be diluted extensively with native shale oil. As the result of these experiments we ascertained that the more volatile oils distilled at a relatively low temperature—such as lamp oil—were devoid of tumour-producing powers, whilst the heavier oils—gas oil, cleaning oil, and lubricating oil—were carcinogenic. One interesting result (with cleaning oil) may be detailed.

> The first sign of neoplastic reaction was a very tiny wart appearing 129 days after the commencement of applications, reaching a diameter of less than 2 mm. eight days later. It was very slightly raised above the skin level but already basal subcutaneous induration was detected, the indurated disc being 5 mm. in diameter. The mouse died at the end of 147 days with an indubitable epithelioma. This is an instance of rapid development of malignancy. Allowing for the two days that elapsed between each scrutiny we can be certain that not more than a week at the most elapsed between the first sign of hyperplasia and the onset of malignancy.
>
> To show how animals differ it may be mentioned that with the same oil one of the mice took thirteen months to develop the first sign of tumour, and some remained refractory for over eighteen months.
>
> (With one of the crude oils active as regards mice, we failed to induce more than temporary small warts in rabbits except in one case in which a papilloma appeared after eleven and a half months increasing slowly till the present time two and a half years since the beginning of treatment, when it is over two inches in diameter and probably malignant. Rats and guinea pigs have proved totally refractory.)

We have thus clear experimental evidence that, with regard to the shale products at any rate, the carcinogenic property is present in the heavier commercial oils. It is highly improbable, however, that the occurrence of mule-spinners' cancer is due to the shale oil ingredients of

* The case has been decided in favour of the plaintiff, a mule spinner who claimed compensation on account of cancer of the scrotum, which he alleged was caused by the nature of his employment.

lubricating oils alleged to have been used during the war I or one thing, the time is too short for epithelioma to have resulted from their use, and for another, we have the information from the Registrar-General that cancer of the scrotum was prevalent amongst mule spinners many years before the war

We were then led to investigate the tumour producing properties of petroleum oils To examine the products of every oil well is out of the question I contented myself by trying the effects of crude oils, untreated in any way, from well in various parts of the world—from the United States, Mexico, Russia, Galicia, Egypt, Persia, Burma, and Borneo In all, sixteen different samples were used, the assumption being that the crude oils would probably contain more of the carcinogenic factors than any of the products refined from them This assumption we now know is not correct For the testing of each sample 100 mice were used and a spot of oil was applied between the shoulders regularly three times a week Unfortunately epidemics during the summer of 1923, combined with the toxic characters of most of the oils were responsible for the loss of large numbers of the animals, but the experiments seemed to indicate that some oils were effective in producing tumours and that others were more or less impotent Tumours resulted in the series which were treated with oils from Borneo, Assam, Egypt, Burma, and Badarpur the last two being the most active, though in no case did a tumour appear till after the lapse of eight months at the earliest In one animal (Badarpur series) we obtained a tumour composed of both epithelomatous and sarcomatous elements, the latter exhibiting a fair amount of melanotic pigment Owing to the small number of survivors I do not feel inclined to attach much importance to the negative results with the other crude oils One of these in particular, a sample from California, was heated and shown by Dr Kennaway to be very *potent in producing tumours* A specimen of fuel oil, which was probably a mixture of the higher boiling fractions of several oils, produced epitheliomata after six months it was, in fact more active than any of the crude oils At the other end of the scale are the vaporizing oils, such as petrol, and with a sample of petrol we failed to produce any tumour growth whatever, even after fifteen months of applications It seems therefore, that the more volatile fractions of mineral oils are devoid of tumour producing properties It should be mentioned that all these oils produce epilation and scurfy dermatitis whether they ultimately induce epithelioma or not

Finally two lubricating oils, of the petroleum group were taken at random With one of these—a light lubricating oil"—no tumours were produced the other—a "medium lubricating oil"—was carcinogenic Lubricating oils of the latter class are almost invariably blends of petroleum products from various sources and contain, in addition, a small percentage of vegetable oils The oil supplied by any one firm is probably not always of uniform composition, *nor does it matter so long as it fulfils the necessary* requirements as to specific gravity viscosity flash point, etc Oils of this class are distilled at about 300° C With the particular sample employed tumours were produced in all the eight mice that survived for eight months

1 Minute wart appeared in eleven month and very slowly increased A second appeared in the fourteenth month Animal died in the sixteenth month Both tumours small and benign

2 A wart accompanied by a shallow ulcer appeared in fourteen month but the mouse was killed and partly devoured by the others a few days later

3 A small papilloma was noticed towards the end of the fourteenth month Progress was slow A second wart arose in the sixteenth month At the end of seventeen months the tumours are still small and benign

4 A little papilloma appeared just a week before the death of the mouse in eleven and a half months

5 At the end of ten months a wart appeared followed by two others in a week's time In twelve and a half months there were two horny papillomata the larger being half an inch high The mouse died in a little over thirteen months The histological examination disclosed an unusual condition Above the level of the skin projected the cornified epithelium while underneath penetrating considerably below the level of the panniculus carnosus there was a flask shaped continuation composed of degenerating whorls of keratin and remnants of muscle fibres the whole being surrounded by a zone of intense inflammatory reaction The appearance suggested a degenerating epithelioma

6 In the eleventh month a shallow ulcer was observed This extended slowly In eight and a half months a subcutaneous nodule the size of a pea was found at the margin of the ulcer A week later the ulcer showed signs of healing and the nodule was smaller The mouse died a few days later and histological examination revealed an epithelioma invading the panniculus carnosus

7 A wart appeared in eleven and a half months over the right scapula In twelve and a half months it measured a quarter of an inch in height by the same in diameter In fourteen months it showed subcutaneous induration A second wart appeared then and grew fairly rapidly The mouse died at the end of sixteen months with *two* epitheliomata

8 In eleven and a half months a small papilloma appeared In twelve and a half months it formed a flesh not cornified wart less than an eighth of an inch across The mouse died in the fourteenth month with a deeply infiltrating epithelioma

Thus, all the mice which survived treatment for eight months or more developed tumours which in three cases certainly, and in another probably, were malignant One of the animals developed two separate epithelomata The lubricating oil is slow in eliciting the neoplastic response much slower than most tars, but once growth is started it is as rapid as *with most other carcinogenic* irritant

Our experiments show, therefore, that refined mineral oils such as are used for the lubrication of machinery are capable of producing skin cancer after long exposure, and they go far to prove the contention of Southam and Wilson that mule spinners' cancer is the result of several years of contact with lubricating oils But why is the scrotum exclusively affected whilst the thighs and the arms escape No satisfactory answer can be given at present To say that the scrotum is more susceptible to the action of the oil is merely to repeat the question A similar difficulty faces us if we attempt to explain the localization of chimney-sweeps' cancer There is still another difficulty Mule-spinning is not confined to cotton similar machines are in use in wool spinning and so far we have no evidence of any undue liability in wool spinners to scrotal cancer In the cotton mills the temperature is high and the air is moist but not so in the woollen mill It may be that in the former the heat relaxes the tissues of the scrotum and allows of the entry of oil into the large opened sebaceous follicles

Accepting the oil as the cause what measures can be taken to prevent the occurrence of this far too common industrial cancer Probably it is impracticable to employ vegetable or animal oils instead of petroleum oils for the lubrication of the spindle, even if we could be sure that they had no carcinogenic property, and an attempt to discover safe mineral oils seems foredoomed to failure It should not be a difficult matter to fit to the machines an effective guard which will prevent the spindle oil being thrown off Possibly a short thin apron impregnated with cellulose might prove useful in protecting the clothes from being soiled But however soon preventive measures are adopted it should be realized that cases of scrotal cancer will still occur, though with diminishing frequency for several years to come amongst the older workmen owing to the delayed action of the irritant

NOTE ON CHIMNEY SWEEPS' CANCER

BY

ARCHIBALD LEITCH M D

Director of the Cancer Hospital Research Institute London

A COMPARISON may be made between the incidence of mule-spinners' cancer and the incidence of the similarly localized chimney sweeps' cancer In the years 1910-12 there were 16 fatal cases in 1913-14 there were 7 (=3 per cent of total) in 1921-22 there were 10 (=9 per cent of all cancer) and in the year there were 4 cases of cancer of the scrotum in chimney sweep This gives an average of 4·5 fatal cases per annum There were in England and Wales according to the 1921 census 5,251 sweeps so that 1 in 1,140 die from cancer of the scrotum every year The incidence, therefore, is higher amongst sweeps than amongst mule-spinners

In a previous paper[1] I discussed the peculiarities of the geographical and anatomical distribution of this form of cancer. It is improbable that the soot acts on the scrotum merely as a mechanical irritant: coal dust in miners does not produce a neoplastic reaction there. It must act in virtue of some active chemical function, and as *corpora non agunt nisi soluta* it is necessary to look for some solvent present in the skin of the scrotum. Passey[2] had succeeded in producing soot cancer experimentally in mice by frequent applications of an ethereal extract. No such powerful solvent is present in the skin, and I suggested that the active principle of the soot was dissolved in the oily secretion of the sebaceous glands of the human scrotum. Sebaceous fat was therefore obtained from human dermoid ovarian cysts, a quantity of soot was mixed with this in the incubator, and the filtrate—a dark brown oil, liquid at body temperature—was applied to the skin of mice and to the scrotum of a number of rabbits. Among the latter animals two developed warts, but the animals bit these off and they have not recurred, in a third a papilloma appeared *after two months, and is still growing*. Amongst the mice we obtained in three cases simple papillomata, the earliest appearing thirty-five days after the commencement of treatment, and in two cases epithelioma. In one of these there was no sign of tumour formation until almost the end of the ninth month, and in the other sixteen and a half months elapsed before the tumour started. In both malignancy supervened shortly thereafter.

The experiments suggest that the sebaceous secretion of the glands of the scrotum is the solvent of the soot in the human subject.

A STUDY OF B. ACIDOPHILUS IN HUMAN FAECES

BY

J. CRUICKSHANK, M.D., and D. W. BERRY, M.C., M.D., D.P.H.

Reader in Bacteriology. Lecturer in Public Health.

(From the Bacteriological Department of the University of Aberdeen.)

The bacterial flora of the intestinal contents shows great variation at different levels of the alimentary tract in health and in disease. The flora of the faeces is seen in stained films bears little resemblance to the organisms which are obtained by the methods of culture usually adopted for the isolation of pathogenic organisms. By the use of a variety of procedures and different media organisms of many types can be isolated, but the results are unsatisfactory regarded from the standpoint of the total flora. In the film stained by Gram's method numerous Gram-positive bacilli and cocci are seen which do not grow on the ordinary agar or broth media. If the hydrogen-ion concentration of these media is altered the growth which results varies considerably, but is generally composed of Gram-negative bacilli of the colon group and streptococci of the *faecalis* type. As a result it has frequently been stated that the majority of the organisms in the faeces are dead. The contrast between the stained film and the growth on ordinary media is most striking in regard to the absence in culture of the Gram-positive bacilli. These bacilli, however, can be obtained in culture when special methods are adopted to prevent growth of *Bacillus coli*. It has been found that this group of organisms is strongly resistant to acid, and that they survive in strongly acid mixtures which kill *B. coli* and most other faecal organisms. The term "*Bacillus acidophilus*" was given by Moro to an organism of this type, but, as Metschnikowsky and Distaso showed, it would be more descriptive to call them acid resistant rather than acidophile. The term "aciduric" has been suggested by Kendall. In the stools of infants Gram-positive bacilli are found in large numbers, and the film contrasts markedly with that of the adult.

A relationship between the occurrence of these organisms and the diet has naturally been suggested, and research workers, particularly in America, have made combined clinical and bacteriological studies which have elicited some interesting facts bearing on this subject. Diets which consist largely of animal protein are associated with faeces in which *B. coli* predominates, whereas diet which is rich in carbohydrates favours the development of *B. acidophilus* types. The terms "proteolytic" and "aciduric" have been used to describe these two types of flora. The administration of lactose and dextrin by the mouth is particularly favourable to the development of an aciduric type of flora. Cannon has used a simple method of determining the type. This consists in making suitable dilutions of the faeces and in enumerating the relative numbers of *Gram negative* bacilli and Gram-positive bacilli in stained smears. This is referred to as the "colon acidophilus ratio." In intestinal stasis and in complete obstruction the *acidolphilus* bacilli rapidly diminish and the flora becomes proteolytic in type. In starvation the same change occurs. Similarly, in most types of diarrhoea the flora is proteolytic, though certain forms of diarrhoea (fermentative diarrhoea) show a distinctly aciduric type of flora. The influence of diet on the flora in experimental intestinal stasis and obstruction has been investigated by several workers. On diets rich in lactose animals survived longer and clinical differences were apparent in the post-operative behaviour, animals on protein diet being listless and refusing food, while those on carbohydrate diet were active and eager for food. The relation of the flora to the reaction of the intestinal contents has been examined. Rettger and Cheplin found no difference in the hydrogen-ion concentration of the faeces, whether the flora was mixed or aciduric in type. Cannon and McNeal, on the other hand, found that there was a direct relationship between the type of flora and the hydrogen-ion concentration of the contents of the caecum, though this was not so apparent when the reaction of the faeces in the lower colon or rectum was considered. With a high animal protein diet the reaction of the contents of the caecum and colon was *p*H 7·0 to 7·1, whereas the addition of lactose in proper proportions led to a reaction in the caecum of *p*H 4·6 with a *p*H 6·2 in the lower colon. In the presence of fermentible carbohydrates both *B. coli* and *B. acidophilus* developed freely, but as the products of fermentation accumulated and the reaction became strongly acid the conditions of growth became inimical to the further development of *B. coli*. In the absence of carbohydrate, *B. coli* assumed a proteolytic activity, and toxic substances, resulting from protein decomposition, were formed.

In the majority of the experiments on the above and similar lines of investigation little attention has been paid to the morphological and cultural characters of the *B. acidophilus*. A review of the recent literature showed that there was much difficulty in regard to the characters by which this bacillus could be recognized. Logan (1914), for example, in an investigation of the intestinal flora of children described *B. acidophilus* and *B. bifidus* under one group although he observed differences in behaviour of different strains. McIntosh, Warwick, and Lazarus Barlow, in a study of *B. acidophilus* occurring in carious teeth, describe two strains differing in cultural and serological characters, to which they have given the name *B. acidophilus odontolyticus*, Types I and II. They are of opinion that these organisms are the cause of dental caries. Rahe (1914), in a study of numerous strains of acid-resistant bacilli from many different sources, described three varieties according to their action in milk and in maltose. In a later communication (1918) he describes four varieties, using glucose, maltose, lactose, sucrose, and raffinose as differential media. During the course of our own work two further papers have appeared which bear on this subject. McIntosh and Lazarus-Barlow, in a further communication on the subject of *B. acidophilus odontolyticus*, give the results of the examination of fifty strains of *B. acidophilus* isolated from the mouth, faeces, and stomach contents of man and animals and of certain strains from milk. These workers comment on the unreliability of fermentation tests, and suggest that differentiation is best made by means of agglutination tests. The results obtained with sixty-seven strains of *B. acidophilus* isolated from human faeces are given by Cannon. All of the strains examined by him fell in the groups described by Rahe.

* This research was carried out with the aid of a grant from the Medical Research Council.

The investigations of which this paper is a short summary, were conducted almost entirely on the stools of normal subjects, adult for the most part

Technique

To tubes of ordinary broth, *p*H 7·6 glacial acetic acid was added in the proportion of 1 per cent. A thick emulsion of the stool was made in salt solution and 0·2 c.cm. added to 5 c.cm. of acetic broth. The tubes were incubated for thirty-six to forty-eight hours, shaken up, and a large loopful sown on plates of ordinary agar. These were incubated for twenty-four to forty-eight hours. With few exceptions growth of acid-resistant organisms in pure culture was obtained, frequently the growth was quite profuse. It was found convenient to allow the plates to stand a day or two at room or incubator temperature in order to bring out differences in colony formation. In none of the experiments was any Gram negative organism encountered, the acid resistant organisms being in all cases Gram positive bacilli or cocci. Single colonies were picked off to ordinary agar, replated if any doubt existed as to purity, and then sown into sugar and other media. It was also found that good results were obtainable by making a heavy inoculation of ordinary broth incubating for twenty-four hours, adding acetic acid, and incubating again for twenty-four hours. In some cases it was found necessary to use the sediment in the acetic broth cultures since if the organisms were scanty, the supernatant fluid might give negative results. There was no evidence in this work that actual growth of *acidophilus* bacilli occurred in the acid broth and we are of opinion that in most cases these organisms merely survived the exposure to the acid. Further it was found that 1 per cent. acetic acid agar plates made directly from the faeces emulsion, did not give growth of *acidophilus* bacilli, although acid-resistant cocci were sometimes got by this procedure. Once the organisms had been isolated growth was readily maintained on ordinary agar. It will be seen later that growth in ordinary broth did not occur, or was very slight, in the absence of fermentable carbohydrate. It is a matter of interest that organisms capable of growth on ordinary agar, and present in considerable numbers in almost any sample of faeces, should not grow on direct plating on ordinary agar or on MacConkey's medium. It would appear that coliform organisms exert an inhibitory effect, but we have been unable to demonstrate this in actual experiment. Only once have we seen colonies of *B. coli* and of *B. acidophilus* on the same plate. In this experiment *B. coli* was present in very small numbers on the plating from acetic broth and was presumably due to an extremely heavy sowing with faeces which had been imperfectly emulsified.

It was found that *B. coli* survived more readily when hydrochloric acid was used in place of acetic acid. Yeasts also survived exposure to hydrochloric acid, but only on one occasion was a growth of yeast recovered from 1 per cent. acetic acid broth culture. In our experience acid resisting bacilli in all cases grew on ordinary peptone agar with a reaction of *p*H 7·6. Twelve of our strains were elected and tested on 1 per cent. acetic acid peptone agar slopes. In no case was growth obtained, whereas control subcultures made at the same time on ordinary agar grew freely in twenty-four to thirty-six hours. Growth of acid resisting bacilli and cocci was tested also on agar slopes of different acidity (*p*H 4, 5, 6, and 7) prepared with hydrochloric acid. Growth took place at *p*H 5 but not at *p*H 4. Comparison was made of anaerobic and aerobic cultures, both of the acetic broth and of agar plate subcultures, but no evidence was obtained of appreciable difference. The organisms were found to be facultative anaerobes. The organisms isolated did not produce indol and did not liquefy gelatin. Early in our work it was obvious from differences in colony formation on agar plate that different strains of acidophile bacilli were present in the same sample of stool. In two experiments ten different strains were obtained from a single sample of a normal stool and in other three cases seven, seven, and six strains respectively were got. As a rule every sample of stool gave growth of acid resistant cocci in addition to bacilli but these strains of cocci are not dealt with in this communication.

The growth of the bacilli on agar was at first extremely delicate, but after a few days many of the colonies assumed a characteristic form. The long-chained bacilli commonly appeared as granular colonies with raised centres and irregular margins, but sometimes as smaller colonies regular in outline and with a ground glass appearance, those bacilli showing curled elements giving colonies in the form of a rosette. Some short-chained varieties showed the feathery colonies frequently described as typical of *L. acidophilus*, others grew as opaque striated colonies raised in the centre or as small clear colonies with smooth edges. The bacilli not forming chains usually developed as small regular or large irregular colonies, and occasionally granular ones surrounded by a ring of what looked like small flattened colonies. Yellowish slightly feathery colonies were the most typical of those bacilli showing filamentous forms, but a few almost colourless granular colonies with a raised ring around the centre of the colony or flat greyish-brown colonies with faintly striated margins were met with. The most striking feature in colony formation was the marked differences in the colonies of bacilli more or less similar morphologically and on plates spread from the primary acetic acid broth several of these types of colony were usually present.

When the purity of a strain of bacillus had been established an agar culture was emulsified in salt solution and by means of a pipette 1 per cent. glucose, lactose, maltose, saccharose, mannite, and dulcite peptone water with the Andrade indicator were inoculated, also litmus milk and broth. An attempt was made by means of the reactions with these media to separate different strains no heed being paid to morphology at this stage. Later in the work a further range of substances—inulin, arabinose, dextrin, and raffinose—were employed. These substances gave a further differentiation within each group. In no instance was any organism isolated which gave gas in any of the media. The formation of acid in fermentable media was usually marked in twenty-four hours. In some media acid production was slow and not well marked. Table I. shows the results obtained and the groups separated by the use of the glucose, lactose, maltose, mannite, saccharose, and dulcite, and the further differentiation of the groups by the use of inulin, raffinose, dextrin, and arabinose. In a recent paper published during the progress of this work, Cannon gives the results of a study of sixty-four strains of *L. acidophilus* and thirty-four strains of *B. acidophilus aerogenes*, obtained mainly from sputum and faeces of normal adults, and a few strains from milk and the intestines of animal. Unneutralized dextrose inulin broth with 0·25 per cent. of glacial acetic acid was used (*p*H 4·8 to 5) after three successive transfers at twenty-four hour interval in this medium plates of which agar dextrose yeast agar were sown. Colonies were picked and transferred to unneutralized glucose yeast broth. The strains of *B. acidophilus* isolated by Cannon all fell in to Rahe's classification (Table III). It will be seen from Table I. that of our fifty-two strains forty-four failed to ferment maltose and four failed to ferment glucose. These strains cannot therefore, be placed in Rahe's classification. Of the two types of bacilli which formed chains a long-chained and a short-chained variety were readily distinguished. Of the non-chained type diplobacilli were frequently found as well as other with no characteristic formation. The majority including the chained types were about the size and shape of the chained *B. acidophilus* described by Moro and others: 0·75 *μ* by 1 to 3 *μ*. Differences in size and shape occurred in the same chain and in some strains almost coccoid forms were present. On this account we had at first difficulty in obtaining what we could regard as pure cultures of certain strains and numerous replatings were carried out. This has also been the experience of McIntosh and Lazarus-Barlow. Howe in his work on dental caries comes to the conclusion that the pleomorphism of *B. acidophilus* has been greatly exaggerated and Cannon is in agreement. Difference in size of the bacilli, both in thickness and length,

In a previous paper[1] I discussed the peculiarities of the geographical and anatomical distribution of this form of cancer. It is improbable that the soot acts on the scrotum merely as a mechanical irritant, coal dust in miners does not produce a neoplastic reaction there. It must act in virtue of some active chemical function, and as *corpora non agunt nisi soluta* it is necessary to look for some solvent present in the skin of the scrotum. Passey[2] had succeeded in producing soot cancer experimentally in mice by frequent applications of an ethereal extract. No such powerful solvent is present in the skin, and I suggested that the active principle of the soot was dissolved in the oily secretion of the sebaceous glands of the human scrotum. Sebaceous fat was therefore obtained from human dermoid ovarian cysts, a quantity of soot was mixed with this in the incubator, and the filtrate—a dark brown oil, liquid at body temperature—was applied to the skin of mice and to the scrotum of a number of rabbits. Among the latter animals two developed warts, but the animals bit these off and they have not recurred, in a third a papilloma appeared after five months, and is still growing. Amongst the mice we obtained in three cases simple papillomata, the earliest appearing thirty-five days after the commencement of treatment, and in two cases epitheliomata. In one of these there was no sign of tumour formation until almost the end of the ninth month, and in the other sixteen and a half months elapsed before the tumour started. In both malignancy supervened shortly thereafter.

The experiments suggest that the sebaceous secretion of the glands of the scrotum is the solvent of the soot in the human subject.

A STUDY OF B. ACIDOPHILUS IN HUMAN FAECES

BY

J. CRUICKSHANK, M.D.
Reader in Bacteriology

AND D. W. BERRY, M.C., M.D., D.P.H.
Lecturer in Public Health

(From the Bacteriological Department of the University of Aberdeen)

The bacterial flora of the intestinal contents shows great variation at different levels of the alimentary tract in health and in disease. The flora of the faeces is seen in stained films bears little resemblance to the organisms which have obtained by the methods of culture usually adopted for the isolation of pathogenic organisms. By the use of a variety of procedures and different media organisms of many types can be isolated, but the results are unsatisfactory regarded from the standpoint of the total flora. In the film stained by Gram's method numerous Gram-positive bacilli and cocci are seen which do not grow on the ordinary agar or broth media. If the hydrogen-ion concentration of these media is altered the growth which results varies considerably, but is generally composed of Gram-negative bacilli of the colon group and streptococci of the *faecalis* type. As a result it has frequently been stated that the majority of the organisms in the faeces are dead. The contrast between the stained film and the growth on ordinary media is most striking in regard to the absence in culture of the Gram-positive bacilli. These bacilli, however, can be obtained in culture when special methods are adopted to prevent growth of *Bacillus coli*. It has been found that this group of organisms is strongly resistant to acid, and that they survive in strongly acid mixtures which kill *B. coli* and most other faecal organisms. The term "*Bacillus acidophilus*" was given by Moro to an organism of this type, but, as Mereshkowsky and Distaso showed, it would be more descriptive to call them acid resistant rather than acidophile. The term "aciduric" has been suggested by Kendall. In the stools of infants Gram-positive bacilli are found in large numbers, and the film contrasts markedly with that of the adult.

A relationship between the occurrence of these organisms and the diet has naturally been suggested, and research workers, particularly in America, have made combined clinical and bacteriological studies which have elicited some interesting facts bearing on this subject. Diets which consist largely of animal protein are associated with faeces in which *B. coli* predominates, whereas diet which is rich in carbohydrates favours the development of *B. acidophilus* types. The terms "proteolytic" and "aciduric" have been used to describe these two types of flora. The administration of lactose and dextrin by the mouth is particularly favourable to the development of an aciduric type of flora. Cannon has used a simple method of determining the type. This consists in making suitable dilutions of the faeces and in enumerating the relative numbers of Gram-negative bacilli and Gram-positive bacilli in stained smears. This is referred to as the "colon-acidophilus ratio." In intestinal stasis and in complete obstruction the *acidolphilus* bacilli rapidly diminish and the flora becomes proteolytic in type. In starvation the same change occurs. Similarly, in most types of diarrhoea the flora is proteolytic, though certain forms of diarrhoea (fermentative diarrhoea) show a distinctly aciduric type of flora. The influence of diet on the flora in experimental intestinal stasis and obstruction has been investigated by several workers. On diets rich in lactose animals survived longer and clinical differences were apparent in the post-operative behaviour, animals on protein diet being listless and refusing food, while those on carbohydrate diet were active and eager for food. The relation of the flora to the reaction of the intestinal contents has been examined. Rettger and Chaplin found no difference in the hydrogen-ion concentration of the faeces, whether the flora was mixed or aciduric in type. Cannon and McNeese, on the other hand, found that there was a direct relationship between the type of flora and the hydrogen-ion concentration of the contents of the caecum, though this was not so apparent when the reaction of the faeces in the lower colon or rectum was considered. With a high animal protein diet the reaction of the contents of the caecum and colon was *p*H 7·0 to 7·1, whereas the addition of *lactose in* proper proportions led to a reaction in the *caecum of p*H 4·6 with a *p*H 6·2 in the lower colon. In the presence of fermentable carbohydrates both *B. coli* and *B. acidophilus* developed freely, but as the products of fermentation accumulated and the reaction became strongly acid the conditions of growth became inimical to the further development of *B. coli*. In the absence of carbohydrate, *B. coli* assumed a proteolytic activity, and toxic substances, resulting from protein decomposition, were formed.

In the majority of the experiments on the above and similar lines of investigation little attention has been paid to the morphological and cultural characters of the *B. acidophilus*. A review of the recent literature showed that there was much difficulty in regard to the characters by which this bacillus could be recognized. Logan (1914), for example, in an investigation of the intestinal flora of children described *B. acidophilus* and *B. bifidus* under one group, although he observed differences in behaviour of different strains. McIntosh, Warwick, and Lazarus Barlow, in a study of *B. acidophilus* occurring in carious teeth, describe two strains differing in cultural and serological characters, to which they have given the name *B. acidophilus odontolyticus*, Types I and II. They are of opinion that these organisms are the cause of dental caries. Rahe (1914), in a study of numerous strains of acid resistant bacilli from many different sources, described three varieties according to their action in milk and in maltose. In a later communication (1918) he describes four varieties, using glucose, maltose, lactose, sucrose, and raffinose as differential media. During the course of our own work two further papers have appeared which bear on this subject. McIntosh and Lazarus-Barlow, in a further communication on the subject of *B. acidophilus odontolyticus*, give the results of the examination of fifty strains of *B. acidophilus* isolated from the mouth, faeces, and stomach contents of man and animals and of certain strains from milk. These workers comment on the unreliability of fermentation tests, and suggest that differentiation is best made by means of agglutination tests. The results obtained with sixty seven strains of *B. acidophilus* isolated from human faeces are given by Cannon. All of the strains examined by him fell in the groups described by Rahe.

* This research was carried out with the aid of a grant from the Medical Research Council.

The investigations of which this paper is a short summary, were conducted almost entirely on the stools of normal subjects, adult for the most part

Technique

To tubes of ordinary broth, *p*H 7·6, glacial acetic acid was added in the proportion of 1 per cent. A thick emulsion of the stool was made in salt solution and 0·2 c.cm. added to 5 c.cm. of acetic broth. The tubes were incubated for thirty-six to forty-eight hours, shaken up, and a large loopful sown on plates of ordinary agar. These were incubated for twenty-four to forty-eight hours. With few exceptions growth of acid-resistant organisms in pure culture was obtained, frequently the growth was quite profuse. It was found convenient to allow the plates to stand a day or two at room or incubator temperature in order to bring out differences in colony formation. In none of the experiments was any Gram-negative organism encountered, the acid resistant organisms being in all cases Gram positive bacilli or cocci. Single colonies were picked off to ordinary agar, replated if any doubt existed as to purity, and then sown into sugar and other media. It was also found that good results were obtainable by making a heavy inoculation of ordinary broth incubating for twenty-four hours, adding acetic acid, and incubating again for twenty-four hours. In some cases it was found necessary to use the sediment in the acetic broth cultures since if the organisms were scanty, the supernatant fluid might give negative results. There was no evidence in this work that actual growth of *acidophilus* bacilli occurred in the acid broth, and we are of opinion that in most cases these organisms merely survived the exposure to the acid. Further, it was found that 1 per cent. acetic acid agar plates made directly from the faeces emulsion, did not give growth of *acidophilus* bacilli, although acid resistant cocci were sometimes got by this procedure. Once the organisms had been isolated growth was readily maintained on ordinary agar. It will be seen later that growth in ordinary broth did not occur, or was very slight, in the absence of fermentable carbohydrate. It is a matter of interest that organisms capable of growth on ordinary agar, and present in considerable numbers in almost any sample of faeces, should not grow on direct plating on ordinary agar or on MacConkey's medium. It would appear that coliform organisms exert an inhibitory effect, but we have been unable to demonstrate this in actual experiment. Only once have we seen colonies of *B. coli* and of *B. acidophilus* on the same plate. In this experiment *B. coli* was present in very small numbers on the plating from acetic broth and was presumably due to an extremely heavy sowing with faeces which had been imperfectly emulsified.

It was found that *B. coli* survived more readily when hydrochloric acid was used in place of acetic acid. Yeasts also survived exposure to hydrochloric acid, but only on one occasion was a growth of yeast recovered from 1 per cent. acetic acid broth culture. In our experience acid resisting bacilli in all cases grew on ordinary peptone agar with a reaction of *p*H 7·6. Twelve of our strains were elected and tested on 1 per cent. acetic acid peptone agar slopes. In no case was growth obtained, whereas control subcultures, made at the same time on ordinary agar grew freely in twenty-four to thirty-six hours. Growth of acid-resisting bacilli and cocci was tested also on agar slopes of different acidity (*p*H 4, 5, 6, and 7) prepared with hydrochloric acid. Growth took place at *p*H 5 but not at *p*H 4. Comparison was made of anaerobic and aerobic cultures, both of the acetic broth and of agar plate subcultures, but no evidence was obtained of appreciable difference. The organisms were found to be facultative anaerobes. The organisms isolated did not produce indol and did not liquefy gelatin. Early in our work it was obvious from differences in colony formation on agar plates that different strains of acidophilic bacilli were present in the same sample of stool. In two experiments ten different strains were obtained from a single sample of a normal stool and in other three cases seven, seven, and six strains respectively were got. As a rule every sample of stool gave growth of acid resistant cocci in addition to bacilli. But these strains of cocci are not dealt with in this communication.

The growth of the bacilli on agar was at first extremely delicate, but after a few days many of the colonies assumed a characteristic form. The long-chained bacilli commonly appeared as granular colonies with raised centre and irregular margins, but sometimes as smaller colonies regular in outline and with a ground-glass appearance, those bacilli showing curled elements giving colonies in the form of a rosette. Some short-chained varieties showed the feathery colonies frequently described as typical of *B. acidophilus*, others grew as opaque striated colonies raised in the centre, or as small clear colonies with smooth edge. The bacilli not forming chains usually developed as small regular or large irregular colonies, and occasionally granular ones surrounded by a ring of what looked like small flatter colonies. Yellowish slightly feathery colonies were the most typical of those bacilli showing filamentous forms, but a few almost colourless granular colonies with a raised ring around the centre of the colony or flat greyish brown colonies with faintly striated margins were met with. The most striking feature in colony formation was the marked differences in the colonies of bacilli more or less similar morphologically and on plates spread from the primary acetic acid broth several of these types of colony were usually present.

When the purity of a strain of bacillus had been established an agar culture was emulsified in salt solution and by means of a pipette 1 per cent. glucose, lactose, maltose, saccharose, mannite, and dulcite peptone water with the Andrade indicator were inoculated, also litmus milk and broth. An attempt was made by means of the reactions with these media to separate different strains no heed being paid to morphology at this stage. Later in the work a further range of substances—inulin, arabinose, dextrin, and raffinose—were employed. These substances gave a further differentiation within each group. In no instance was any organism isolated which gave gas in any of the media. The formation of acid in fermentable media was usually marked in twenty-four hours. In some media acid production was slow and not well marked. Table I. shows the results obtained and the groups separated by the use of the glucose, lactose, maltose, mannite, saccharose, and dulcite, and the further differentiation of these groups by the use of inulin, raffinose, dextrin, and arabinose. In a recent paper published during the progress of this work, Cannon gives the results of a study of sixty-four strains of *B. acidophilus* and thirty-four strains of *B. acidophilus aerogenes*, obtained mainly from sputum and faeces of normal adults, and a few strains from milk and the intestines of animals. Unneutralized dextrose infusion broth with 0·25 per cent. of glacial acetic acid was used (*p*H 4·8 to 5). After three successive transfers at twenty-four-hour interval in this medium plates of whey agar or dextrose yeast agar were sown. Colonies were picked and transferred to unneutralized glucose yeast broth. The strains of *B. acidophilus* isolated by Cannon all fell in to Rahe's classification (Table III.). It will be seen from Table I. that of our fifty-two strains forty-four failed to ferment maltose and four failed to ferment glucose. These strains cannot therefore be placed in Rahe's classification. Of the two types of bacilli which formed chains a long-chained and a short-chained variety were readily distinguished. Of the non-chained types diplobacilli were frequently found as well as other with no characteristic formation. The majority including the chained types were about the size and shape of the chained *B. acidophilus* described by Moro and others, 0·75 *μ* by 1 to 3 *μ*. Differences in size and shape occurred in the same chain and in some strains almost coccoid forms were present. On this account we had at first difficulty in obtaining what we could regard as pure cultures of certain strains and numerous replatings were carried out. This has also been the experience of McIntosh and Lazarus-Barlow. Howe in his work on dental caries comes to the conclusion that the pleomorphism of *B. acidophilus* has been greatly exaggerated and Cannon is in agreement. Difference in size of the bacilli both in thickness and length,

Strains denoted by Inf were derived from infant faeces * Indicates strains from which agglutinating sera were prepared

frequently necessitated our replating cultures after isolation in order to ensure purity. Although some variations in morphology were found in recent subcultures pleomorphic forms appeared more frequently in older (four to six weeks) cultures, and seemed to be of the nature of involution forms. In some of the older cultures swollen and club-shaped bacilli were also present. Old cultures of some strains showed slight beading or bipolar staining, and the power of retaining Gram's stain was decreased, many definitely Gram negative elements being present. Angled and straight diplobacillary forms were numerous in many of the strains, and parallelism or palisade grouping was common. One peculiar characteristic noted in three strains and especially prominent in one (Infant C 4) was a very marked curling of the bacillary elements. Many of these curled forms were in pairs, and when much swollen simulated large diplococci. When in chain formation the curled forms gave an appearance not unlike spirilla. The filamentous forms were seen occasionally and were of two kinds—one uniform in width, corresponding to the thickness of the bacilli and the other very irregular in thickness and in outline.

Considerable differences were found also by McIntosh and Lazarus-Barlow in their later work, when they extended their range of sugars from four to ten. The fermentation reactions of a number of our strains have been tested on more than one occasion at intervals of one to three months after isolation. No change in the results was found. McIntosh and Lazarus-Barlow have drawn attention to some alteration in sugar fermentation, particularly in regard to saccharose fermentation, three to twelve months after isolation.

As the fermentation reactions of these organisms were so varied, we commenced the preparation of agglutinating sera by intravenous injection of living cultures into rabbits in order to determine the serological relationships. Agglutinating sera from five strains—C 30, Infant C 4, C 6, C 24, and B 5—corresponding to five different groups, have been prepared. The titres of these sera for the homologous organisms varied from 1 in 800 to 1 in 12,800. The results of agglutination tests carried out down to the present time may be summarized thus.

Serum C 30 agglutinated up to titre the strain An 2 which was isolated by anaerobic culture and appears in all respects identical with C 30. This serum also agglutinated *B. acidophilus odontolyticus*, Type I (kindly supplied to us by Professor McIntosh), in dilution of 1 in 800, the full titre of the serum for the homologous organism being above 1 in 1,600. Both C 30 and An 2 are very long-chained varieties, but Type I of McIntosh, Warwick and Lazarus-Barlow does not form long chains, nor do its sugar reactions tested on our media, correspond to those of C 30 and An 2. Serum C 30 did not cause agglutination of any of the other organisms in the same group, as determined by the original sugar reactions. Serum Infant C 4 agglutinated no other of four strains tested. Serum C 6 agglutinated to full titre strain C 11 which gave exactly similar fermentation reactions to those of the homologous organism. No other strain tested was agglutinated. Serum C 24 agglutinated strain Infant C 11 which is also identical with the homologous strain. Serum B 5 partly agglutinated strain G D 6, which differs in fermentation reactions from the homologous organism. The titre of the serum was 1 in 12,800, but G D 6 agglutinated only up to 1 in 800. This reaction, as well as the agglutination of *B. acidophilus odontolyticus* Type I, seemed to indicate the presence of group agglutinins, but on the whole it would appear that the many acid resistant bacilli isolated by us from the faeces differ as widely in the serological reactions as they do in fermentation properties. It is noteworthy that the agglutination reactions which have so far been carried out do not show the group reactions which McIntosh and his collaborators claim to exist within the *acidophilus* group. A number of our strains very closely resemble *B. bifidus* recently isolated by Dr Robert Cruickshank, and one of these strains (C 24) agglutinates to full titre and shows marked absorption of agglutinins when tested with *B. bifidus* antiserum. The sugar reactions of *B. bifidus* and of strain C 24, however, do not correspond.

Difficulty in classification of aciduric organisms by cultural and biochemical reactions has apparently been somewhat general experience. Pahe criticized the work of Grigoroff, Cohendy, Bertrand, and Duchacek on the fermentation of sugars by *B. bulgaricus*, and regards their results as of doubtful value owing to lack of agreement. He stated that there was "little known of the action of *B. acidophilus* on the different sugars." Pahe himself must have experienced the same difficulty. In a paper published in 1914 he divided fifty four strains into three groups, one of which did not ferment maltose, while in 1918 he made four groups all of which ferment maltose.

TABLE III.—*Pahe's Classification.*

Type	Maltose	Glucose	Lactose	Sucrose	Lævulose
A	X	X	X	X	−
B	X	X	X	X	−
C	X		−	X	−
D	X	X	−	−	−

Of our forty four strains only six [illegible] maltose and four did not ferment glucose. A preliminary cultivation of these acid tolerant bacilli was found necessary, as growth did not occur in sugar media unless the carbohydrate present was fermented by the bacteria. Moreover, some of the cultures did not grow in ordinary peptone broth, but required differing from many of the other [illegible] teeth by McIntosh, Warwick and Lazarus-Barlow [illegible] which showed uniform turbidity in broth. The [illegible] strains which showed variable growth in broth and a

slight deposit at the bottom of the tube, and the medium became turbid or granular on shaking. All strains, on the other hand, grew readily on ordinary nutrient agar pH 7·6. Some of the strains, especially the long-chained varieties, were difficult to emulsify in salt solution. All strains grew profusely in glucose broth, causing turbidity or a heavy deposit, but did not grow appreciably better on glucose agar than on ordinary agar. In connexion with this lack of growth in unfermented carbohydrate media, it is interesting to note that the feeding of lactose and dextrin to experimental animals was found by Torrey and by Cannon to result in a great increase in the aciduric bacilli in the intestinal flora. In our table of results it will be seen that several of the aciduric bacilli which have been isolated by us fail to attack these two substances. Nine of our strains fermented dextrin but not lactose, seventeen fermented lactose but not dextrin, thirteen fermented both, and thirteen had no action on either of these sugars. The production of acid in some carbohydrate media was slow with some strains, and required three to five days' incubation.

Practically all strains produced acid and clot in litmus milk. Decolorization of the litmus from the bottom of the tube upwards was a noteworthy feature. The clot was usually of a soft consistence, and easily spread over the sides of the tube by shaking. With some strains, however, the clot was quite firm. In one case only was considerable amount of whey expressed. Most strains clotted milk in twenty-four hours, but some required three to five days. Torrey reported attempts to shorten the clotting time of more slowly acting types by repeated transplants into milk medium, but could not hasten clotting. Similar procedure with some of our slow-clotting strains was also unsuccessful.

No relationship between morphology and sugar or milk reactions could be established. Table IV gives the fermentation reactions of all strains showing long chains. The only common characteristic is the production of acid from glucose. Similarly, in Table V there is no correspondence among the short-chained varieties. Among those not belonging to the chain-forming groups there is a like lack of uniformity. Of the sugars tested glucose was fermented by the greatest number of the strains, and dulcite, maltose, mannite, and raffinose by only a few.

Summary

The results of our work indicate that the acid-resistant bacilli in adult or infant faeces show a considerable range of morphological appearances. An attempt has been made to group these organisms by their biochemical reactions and to determine some of their serological relationships. It is suggested that the term "*B. acidophilus*" covers a considerable group of organisms and that numerous strains may exist even in one sample of stool.

THE IMPLANTATION OR ENRICHMENT OF BACILLUS ACIDOPHILUS AND OTHER ORGANISMS IN THE INTESTINE

By

RALPH P. SMITH, M.B., Ch.B., D.P.H.

(From the Pathological Department of the University and Western Infirmary, Glasgow.)

The view that it was important to establish an intestinal flora consisting of bacteria which cause souring of milk was emphasized by Metchnikoff, who thought by this means many benefits could be conferred involving prolongation of life. Sour milk therapy has been investigated with great thoroughness by American workers (Rettger and Chaplin,[1] Gompertz and Vorhaus,[2] Bass,[3] Kopeloff and Chaney[4] and others).

The organism principally used is of the *B. acidophilus* type of Moro,[5] this is not the organism most prevalent in the faeces of young infants, especially those breast-fed, which harbour *B. bifidus* in almost pure culture. But the conditions of growth of the latter in culture are somewhat restricted, therefore *B. acidophilus* has been mainly used. In preparing such cultures it is important that Rettger and Chaplin's[6] directions should be followed in order that palatable products may be obtained.

Morphological Characters of B. acidophilus

In Gram-stained smears from human faeces and from milk and whey-broth cultures, *B. acidophilus* appears as a rather long, stout Gram-positive rod, characteristically

* The expenses of this investigation were defrayed by the Medical Research Council.

curled towards the ends. Great variation occurs in length—shorter forms alternate with long filamentous forms, some of which may be partially Gram-negative, especially in old cultures, but also frequently in faecal films. Some varieties of *B. acidophilus* occur as short Gram positive bacilli with a tendency to chain formation, especially on isolation from rats' or dogs' faeces. In cultures on whey-agar two types of colony of *B. acidophilus*, designated by Rettger and Horton[6] as Y and X, are seen frequently side by side. These are easily recognized under the low power of the microscope. The former have a decidedly fuzzy appearance, and are indistinguishable from the colonies of *B. bulgaricus*, while the Y type is small round or spindle-shaped and is only partly fringed, and at times appears almost perfectly smooth. The latter colonies may be designated crab like. The two appear to be interchangeable.

The Y colonies can be differentiated from those of *B. bulgaricus* by the fact that *B. acidophilus* produces acid in 1 per cent. maltose broth after incubation at 37° C. for forty-eight hours whereas *B. bulgaricus* does not.

Isolation of B. acidophilus from Faeces

Agar containing 1 per cent. peptone and 2 and 4 per cent. lactose proved efficient in the isolation of the aciduric organisms from dogs' and rats' faeces, but did not give quite so good results in the case of human faeces, for which whey-broth, whey agar (Rettger and Cheplin[1]), and liver glucose agar (Torrey) were better. On the latter medium *B. acidophilus* colonies appear as small fluffy deep colonies resembling a fleck of cotton, or as flat dingy or globular colonies with serrated edges, and are distinguishable from *B. bifidus* colonies which are raised, more or less globular and buff or reddish brown in colour. As in the case of *B. bifidus*, *B. acidophilus* is acid tolerant rather than acidophile under cultural conditions.

Generally speaking the isolation of aciduric organisms is much easier in the case of animal faeces. On numerous occasions considerable difficulty was experienced in the isolation of these organisms from human faeces even when large quantities of milk soured by *B. acidophilus* were being administered and when direct Gram stained smears from the faeces showed a considerable proportion of such bacilli.

Experimental Feeding with B. acidophilus Milk to Human Typhoid Bacillus Carriers: the Effect on the Intestinal Flora

The ingestion of recent cultures of *B. acidophilus* in milk—two and a half pints a day, a third of this amount being drunk thrice daily between meals—in addition to a mixed diet containing approximately 250 to 300 grams of carbohydrate, caused within four days such a transformation of the ordinary mixed intestinal flora of two typhoid and one paratyphoid carriers that the predominant organism was of the *B. acidophilus* type (80 to 90 per cent. of the organisms present in Gram stained films). The number of coli-form colonies on MacConkey agar plates was considerably reduced during the period of administration of the milk. On discontinuance of milk feeding the ordinary mixed flora reappeared in four or five days, while after forty-eight hours no growth of *B. acidophilus* was obtained in whey agar or whey broth. Even after feeding with *L. acidophilus* had been discontinued for five days, however, bacteria of this type were still present in small numbers in Gram stained films.

In order that, if possible, conditions favourable for the persistence of *B. acidophilus* in large numbers might be established, commercial lactose in doses of 6 ounces a day in three equal doses between meals was given along with the amounts of *B. acidophilus* above mentioned to two carriers. After feeding with *B. acidophilus* was discontinued the lactose was continued for six weeks in one case, a satisfactory persistence of *B. acidophilus* occurred (abundant *acidophilus* present six weeks after stoppage of *acidophilus* milk feeding), but with the other only slight delay in disappearance of the organisms resulted (less than 5 per cent. of the organisms in stained films were of *acidophilus* type one week after stoppage of *acidophilus* milk feeding).

Additional Factors on which Implantation Depends

Ingestion of lactose—apart from feeding with *acidophilus* milk—in large quantities (6 ounces a day) can transform the flora, but the results obtained are not so striking as with *B. acidophilus* milk and are somewhat variable, a partial failure being met with in one of the cases tested. Laxatives in conjunction with lactose feeding appeared to aid the transformation, apparently by hurrying on the contents of the small intestine so that the lactose is not absorbed and is available in the lower reaches of the bowel where the aciduric organisms apparently multiply. The transformation effected by means of a high calorie carbohydrate diet by itself is not so complete as that brought about by *B. acidophilus* feeding in man, but is quite successful in the case of rats.

Implantation of B. bulgaricus

Acclimatization of this organism in the intestine of man after oral administration has been claimed by Metchnikoff and his followers (Cohendy[8] Belonow[9] and Leva[10]) but this has not been substantiated by other investigators (Luerssen and Kuhn[11] Herter and Kendall,[1] Distaso and Schiller[12] Rahe[13] Hull and Pettger[14] and Rettger and Cheplin[1]). Half a litre of sterile milk infected with *B. bulgaricus* and prepared in the usual way was given to three different persons but in no case was it possible to isolate the organisms from the faeces in spite of calomel being given the previous evening. The failure in repeated attempts to implant *B. bulgaricus* in the intestine of man may be due to the fact that unlike *B. acidophilus*, it is not a normal inhabitant of the human intestine.

Feeding with Special Types of B. coli

For a period of a month two enteric carriers were fed with amounts up to 4 ounces thrice daily of milk inoculated with *B. coli* of the *lactis aerogenes* variety and incubated at 37° C. for twenty-four hours. The strain employed in these experiments was isolated from the faeces of a *B. paratyphosus* B carrier. As there was no marked alteration of the intestinal flora and no predominance of the characteristic colonies of *B. lactis aerogenes* a vaccine was prepared of the organism which was injected into one of these patients subcutaneously commencing with 5 millions and rising by approximately doubling doses to 1,000 millions the doses being given at two to four day intervals. At the same time feeding with the organisms was continued as before. The flora was now so transformed that *B. lactis aerogenes* was present almost in pure culture in direct MacConkey agar plates from the faeces. After stoppage of the administration by mouth of *B. lactis aerogenes* only small numbers of these were found for the next two or three weeks, showing that no permanent implantation had taken place. A similar failure was experienced on feeding milk cultures of an inosite-fermenting type of *B. coli* in the same case. Thus the experimental feeding of bacteria not normally present in the intestine failed to cause their implantation in the intestine as has been generally found. But after vaccination implantation occurred for a time. This result appears to agree with that of Raubitschek[15] who was able to implant *B. prodigiosus* and other organisms in the intestines of rats and dogs after preliminary immunization by a vaccine of the same organism.

The Effect of B. acidophilus and Lactose Feeding etc. on the Reaction and Consistency of Faeces

The reaction of the faeces was not influenced by the administration of *L. acidophilus* milk or lactose but appeared to be influenced by milk inoculated with *L. lactis aerogenes* and *B. coli* (inosite fermenting type) being rendered acid thereby. The character of the faeces was soft moist odourless and of a light yellow colour during the taking of milk soured by *L. acidophilus* or the ingestion of lactose in large quantities. This was very evident in comparison with the faeces of other typhoid carriers under observation and of the same carriers under other regimes whose stools were frequently hard formed fair in colour rendering the isolation of the enteric organisms much more difficult if not impossible.

Conclusions

1 Implantation or enrichment of aciduric organisms (*B acidophilus* type) in the intestine occurs in the human subject as a result of feeding with cultures—for example, in milk, this result is facilitated by administration of lactose and diet rich in carbohydrate, but these alone are not so effective

2 The organisms rapidly disappear when feeding with cultures is stopped But they may persist in some cases as a result of continued ingestion of lactose

3 Implantation of foreign types of *B coli* may succeed provided that vaccination with the organism is practised along with feeding with cultures (in confirmation of Rubitschek)

4 The predominance of *B acidophilus* in the intestinal flora as a result of ingestion of cultures seems to relieve constipation, but does not notably affect the reaction of the faeces

5 The excretion of typhoid and paratyphoid bacilli in the faeces by chronic carriers was not influenced, although *B coli* was to a great extent suppressed by feeding with *B acidophilus* milk

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PULMONARY EMBOLISM

In reference to Mr Lockhart-Mummery's paper on the above subject published in the British Medical Journal of November 8th (p 850), the following case of death from pulmonary embolism following reduction of a hip dislocation is of interest

A collier aged 39 early in the morning of March 22nd 1923 was injured underground by a fall of stone weighing several hundredweights on the back of the right thigh He was taken to the local hospital where under an anæsthetic an attempt was made to reduce a dislocation of the right hip This failed and on the same day he was sent to the Royal Infirmary Cardiff and admitted at 5 p m An obturator dislocation of the right hip was found and an anæsthetic given immediately First attempts at reduction resulted in the movement of the head of the femur to the back of the acetabulum a further attempt produced reduction The patient was put to bed with the legs tied together The condition and reduction were confirmed by radiographs

On March 23rd the patient had much pain in the right hip and difficulty in passing water The following day the right ankle was very swollen and blue there was general swelling of the right limb On March 27th the pain was less and the ankle swelling was going down

On April 1st at 3 p m he had sudden pain in the right side of the chest with marked cyanosis and dyspnœa and blood stained, frothy fluid expectoration the pulse was weak and rapid At 6 p m the breathing was more laboured and the pulse weaker He died at 7 30 p m

At a full necropsy carried out by Dr H A Haig on April 2nd the following conditions were found Embolus in the form of a 'riding clot' —that is astride the bifurcation and blocking both branches of the pulmonary artery, thrombosis adjacent, marked congestion and œdema of both lungs heart enlarged both ventricles dilated, subperitoneal tissue in region of sternum and right iliac fossa œdematous, *ante mortem* clot in right external iliac vein The pulmonary specimen is in the pathological museum at the Royal Infirmary

The primary injury and the two manipulations under anæsthesia bruised the adjacent femoral vein, and this and the subsequent immobility produced stasis and thrombosis there, these spreading to the external iliac vein On the tenth day after the injury a portion of the clot in the external iliac vein was detached and carried to the bifurcation of the pulmonary artery, blocking both its branches The resulting strain on the heart from obstruction to the circulation between its right and left sides caused death in four and a half hours

Sepsis is ruled out as a causative factor in this case

Royal Infirmary, Cardiff A W Sheen

DERMATITIS CAUSED BY PEDICULOIDES VENTRICOSUS

The general manager of the Docks recently reported to the Medical Officer of Health of Bristol the occurrence of a highly irritating rash among dock labourers engaged in unloading barley from Morocco, which was attributed to spicules penetrating the skin

On visiting the ss *River Lagan*, one of the ships concerned, a number of labourers were found to have a closely-set but discrete papular rash on the arms, neck, and face The back, chest, and abdomen were also affected, but to a lesser degree, and here the rash was more widely distributed In no case were the legs affected No constitutional effects had ensued among the patients examined

The barley was of excellent quality, and to the naked eye very clean Some of it was screened, and the dust was found on microscopic examination to contain the mite *Pediculoides ventricosus*,[1] which appears to be a parasite of the caterpillar of the cotton moth In some samples only one or two were discovered after a long search, while in others mites were present in practically every field For an unknown reason, only females were found, no males or gravid females being present in these specimens A long and careful search is necessary, as many negative samples may be followed by one containing large numbers of mites

The disease shows little tendency to spread from one person to another, although the labourer's family may become infected apparently if much dust is carried home on the clothes The mite does not burrow under the skin, and does not persist for long on the human body Soothing ointments and bathing with warm water containing soda were recommended, and as a prophylactic measure smearing the exposed parts with grease was advised, followed by a bath after work, a procedure which is reported to have produced good results in America

Dust blown from the barley will apparently carry the mite and so cause the disease We are informed that in another part the inhabitants of some cottages quite close to the dock where Moroccan barley was being unloaded developed the disease, although not in contact with the grain The captain and the mate of the *River Lagan* were affected, although they had not actually handled the barley This is readily intelligible when one sees the great numbers of mites present in small quantities of the dust

The name "barley itch" is to be deprecated it gives patients the impression that they are suffering from the much more serious ailment to which the name "itch" properly belongs and of which the pathology is essentially different, although it is also caused by a mite In addition the parasite is found on other vegetable substances, giving rise to a similar dermatitis—for example, cotton seed, is reported by Nixon,[2] to whose paper I would refer those who wish to see some of the best illustrations published of the mite

Although of little harm beyond the annoyance caused by the itching and the consequent loss of sleep, the disease is of considerable economic importance Dock labourers require up to 10s a day extra pay when handling this grain, and certain port authorities are even considering whether they shall refuse to allow it into their docks at all The majority of labourers who handle the grain develop the disease, but a few exceptional individuals seem to be immune The problem is also of some interest owing to the fact that recently there has been a large increase in the amount of barley imported from Morocco

We are indebted to Dr Henderson, of the Department of Zoology in Bristol University, for confirming our opinion as to the identity of the mite

CONCEPTIONS OF CONSCIOUSNESS

Dr C S Myers devoted his presidential address in the Section of Psychiatry of the Royal Society of Medicine on November 11th, to certain views on the subject of consciousness, gathered, he said from a study of pure psychology, but which he hoped might be of service in the allied field of medical psychology

Dr Myers described the chief or one of the chief functions of consciousness as the selection by the individual of alternative stimuli If, owing to the uniformity of external conditions or—what came to the same thing—the immobility of the organism, the individual was unable to alter its relation to its environment, consciousness could hardly arise The object of consciousness was to maintain a favourable environment and avoid an unfavourable But if the consciousness was to act effectively in its selection relatively small variations in the environment must differ appreciably in the reactions they produced It was also the task of consciousness to co-ordinate all the past and present experiences of the organism so as to give direction to its future activities and choices of environment Dr Myers instituted a parallel, in the realm of mental activity, to the two forms of activity of living substance—the one, intensive and momentary, the other, moderate and prolonged The contractions of striated muscle illustrated the first of these, and of unstriated the second Was it too fanciful, he asked to try to distinguish these two forms throughout mental activity even up to the highest conscious processes—on the one hand, the momentary and so to speak, mechanical acts of expression in general, and on the other hand, the long continued and relatively persistent sets of attitudes or mental postures of a directive character? He rather deplored the exaggerated importance now attached to the affective consciousness which had led even to such things as a slip of the tongue or the process of forgetting being invariably attributed to emotional conflict and inhibition It was also held—a view which he was unable to accept in its entirety—that there was a sort of common fund of affective energy—a single *libido*—that could be drained off into one or other channel of mental activity in such a way that what one channel gained necessarily impoverished the others Dr Myers held that it was unreasonable to suppose that the 'energy" informing human acts was derived solely from affects, although it might be considered that—using the term in its widest sense—the attitudes or mental postures served as keys to unlock the energies resident in the acts It was unreasonable also, in his opinion, to suppose that acts depended on a kind of drainage from one channel to another The mind was not comparable to a vast sewerage system in which the active channels drained off energies from channels which were in so far rendered inactive The act of inhibition involved as much work as that of excitation

Finally, Dr Myers turned to consider the nature of consciousness itself There was a time he said, when mind was regarded as the product of the brain, just as bile was regarded as the product of the liver this was succeeded by an age when mind and living matter were regarded as absolutely different in kind so that it appeared absurd to compare mind with bile as a secretion or living substance From this there grew up on the one side a theory of psycho-physical parallelism and, on the other of interactionism in which the mental and physiological processes were regarded as in some respects interdependent and according to circumstances, influencing and controlling each other Times had now changed It was no longer possible to regard matter as composed of inert atoms The structure of the atom was revealed as a constellation of ions, each of which appeared to be a charge of electricity Matter was coming to be regarded as a manifestation of electrical forces—in other words, as the product of activities What, then, of mind? Was not this likewise the product of activities? Was the difference between mind and matter so fundamental as it appeared a century ago? On considering mind and living matter, the distinction was reduced almost to vanishing point Essentially the same purposive directive characteristics which distinguished living from dead matter distinguished also—raised to a higher power—mental activity from the activity of other living tissues

TREATMENT OF EMPYEMA

At a meeting of the Liverpool Medical Institution on November 6th a discussion on the treatment of pleural empyema was opened by Mr Thelwall Thomas

Mr Thomas alluded to a discussion in 1893, when he brought upon himself serious criticisms for daring to advocate excision of a portion of rib to facilitate free drainage He discussed empyema with and without pneumonia, and emphasized the necessity of repeated aspiration in severe cases of empyema, complicated with pneumonia, to relieve serious symptoms of toxæmia and a physia before resorting to incision—a line of treatment confirmed during the severe war epidemic He strongly advised local anæsthesia, both as a preliminary to exploratory puncture and as the only method of anæsthesia for the subsequent operation The site of election was below the angle of the scapula, a portion of the eighth or ninth rib being excised and the pleural opening being made sufficiently large to admit two fingers and facilitate the removal of masses of fibrin Since the routine performance of this operation chronic empyema had been much less frequent Mr Thelwall Thomas mentioned the value of x rays examination in doubtful cases Tubes for drainage should be half an inch in diameter at least he deprecated the use of safety pins as "land anchors" for the tube suggesting instead a strong hairpin pushed through the tube and the limbs bent at right angles Chronic cases necessitating Dakin treatment, or plastic operations, had become rare owing to increased efficiency in drainage antiseptic dressings should be used Exercises to expand the lungs and good feeding were essential The operation of incision drainage and immediate closure he considered severe and uncertain in its results

Mr John T Morrison confined himself to discussing how the development or chronic empyema could be prevented This might be looked at from two points of view—the early expansion of the lung, and the prevention of infection The first should be encouraged from the start The ideal method—primary closure of the wound—being still too risky for general use, valvular drainage should be employed Personally he favoured connecting up a short wide drain with a tube hanging over the bed, the tube end passing under the surface of fluid in a bottle on the floor The tissues must, of course, fit snugly round the drain This made an air-tight and water tight joint so that there was no necessity to touch the dressing for five to eight days The prevention of mixed infection was impossible if the wound remained open If possible the drainage tube should be removed at the first dressing it might be as early as the third day to the fifth if the lung had expanded and adhered to the parietes round the drain as it often did The early removal of the drainage tube appeared to him to be the safe and reasonable compromise between immediate suture and prolonged drainage of the chest

Sir James Barr dealt with the physics concerned When an operation for the evacuation of the pus was necessary the object should be to prevent, as far as possible the collapse of the lung The incision should be made posteriorly, as low as thought desirable and in a line with the lower angle of the scapula The patient should lean towards the affected side and an assistant should compress that side of the chest A short tube should be kept in for a few days so as to prevent the wound closing and the wound should be covered with a piece of sterilized oiled silk so as to act as a valve to prevent air entering but allowing pus to escape The patient should frequently blow into a Woulff's bottle or piece of rubber tubing to keep the lung expanded When a rise of temperature occurred the surgeon frequently concluded that it was due to lack of free drainage and retention of pus he then proceeded to enlarge the wound and work further and further inwards

rise of temperature was nearly always due to secondary infection of the wound When the wound was dry and glazed constant irrigation should be at once adopted, either with Dakin's tubes, or by immersion in a warm saline bath The water in the bath should contain 0 9 per cent of sodium chloride Attention to minute details was necessary for success

Mr K W Monsarrat considered that the appropriate treatment of empyema was dictated by the type of infection in each case In streptococcal cases in early thoracotomy was often indivisible In tuberculous cases the results of open operation were usually disappointing, sinuses in these cases tended to persist indefinitely In pneumococcal cases he held that there was no rival to adequate drainage, tube drainage being dispensed with at the earliest possible moment He did not use any special measures, he considered that the essentials of technique were in opening wide enough for the evacuation of coagulum masses and a tube large in diameter and short in length Examination of the discharge was the best guide in choosing the time for dispensing with the tube

Dr Hubert Armstrong recalled the danger of acute oedema of the lung and syncope in exploratory puncture, and denied that it could be averted by previous local anaesthesia There was no such danger in the exploration of an empyema, but only when the needle entered the lung in chronic pneumonia He considered it advisable to aspirate in cases where the fluid was only turbid, and to postpone open operation till it had become frankly purulent The extremely low operation was not without danger of injury to the diaphragm and consequent infection of the peritoneum

Dr J C Matthews referred to those cases, usually following pneumonia, in which aspiration produced a thin turbid fluid with a high bacterial content It was well recognized that these patients, if submitted to immediate operation, became very ill he suggested that this was due, not so much to the infective nature of the fluid, but to the fact that in the absence of adhesions between the lung and chest wall operation induced a complete pneumothorax with consequent collapse of the lung and displacement of the mediastinal contents to the opposite side

DEEP X-RAY THERAPY

At a meeting of the Brighton and Sussex Medico-Chirurgical Society on November 6th, Dr L F Maynard, the President, in the chair, Dr W Barrington Prowse read a paper on deep x-ray therapy

Dr Prowse commenced by pointing out that though x-ray treatment, like surgery, had its definite limitations, yet in many cases it might alleviate suffering or prolong life when no prospect of cure was present The main purpose of his paper was the subject of x rays in relation to malignant disease, in particular he wished to speak of the more scientific and accurate applications of x rays for therapeutic purposes, especially as employed at Erlangen The work of Professors Seitz and Wintz at that university had raised deep therapy to the rank of a scientific and accurate procedure, and had led to greatly improved results Even by the older methods relief of pain, healing of ulcerated surfaces, disappearance of a growth—at any rate for a time—had been effected, but measurements and dosage were variable Now the dose could be measured fairly accurately both on the surface of the body and at given depths, and the now established reactions of normal and diseased tissues to different quantities of rays gave them some basis for the dosage Apparatus also had been improved, rendering possible the use of the necessary heavy and accurate dosage of rays of sufficient penetrating power and homogeneity X rays had a profoundly destructive action on all tissues when administered in sufficient quantity, in smaller doses they appeared to stimulate, though this had been disputed The action of x rays on living tissues varied in degree, young and rapidly growing cells, such as those of embryonic type, were more susceptible than older cells of fixed type The cells of new growth, being largely of embryonic type, were, in varying degree, more susceptible than most of the body cells of fixed type

Seitz and Wintz, at Erlangen, had determined the quantities of x rays which produced biological changes in tissues, normal or diseased, while Krönig and Friedrich of Freiburgm, working on different lines, had similar results, giving the same reactive sensitiveness for individual tissues So was established a basis for estimating the necessary dosage in deep x-ray therapy He defined the latter as being the administration of an accurately measured quantity of rays, for curative purposes, to the whole of a diseased area within the body, such quantity being the minimum which would destroy the vitality of the diseased tissue to which it was applied In this accurate measurement lay the difference between this and the older methods Depth was variable, the tissue treated might be in the centre of the body or at the surface He did not like the word "intensive," ignoring measurement and conveying the impression of extreme intensity, though this was no greater than in the older methods The treatment was intensive in the sense that it aimed at giving the full necessary dosage within a short time, instead of in divided doses over a long period Dr Prowse thought that the immediate application of the total dose was the method of choice, as a rule, when dealing with an existing malignant growth, except where there were positive contraindications Ten years ago it had been noticed that malignant growths exposed to x rays gradually suffered diminution of their sensitiveness to the rays, and Sidney Russ had recently further established, by experiments on rat sarcoma, that this acquired resistance was handed down through many generations of cells from those originally irradiated This was a strong argument in favour of the immediate application of the total dose The single dose was more accurate, smaller in quantity in the end, and saved time, which was important in dealing with cancer Those who advocated divided dosage laid stress on the fact that recovery from these doses was more rapid in the normal tissues than in the tumour, *on the* absence of x-ray sickness, and on the *great general dis*turbance of the body frequently seen after the single dose, changes in the blood, and possible injury to healthy organs These latter dangers might also be present in the divided dose Dr Knox had suggested that the control of cancer and other diseases by radiations in divided doses should be aimed at, but was this possible? Many cases of cancer had been checked in their progress by x-ray treatment carried on at intervals, but in the end the patients had succumbed, after a time x rays had appeared to lose their power He did not suggest that the single lethal dose was applicable to every case Each case must be considered on its merit, and the arguments against the single massive dose had much weight in cases other than those of existing malignant disease The prime object of the Erlangen treatment of cancer cases was the destruction of the vitality of the cancer cells There followed breaking down of the tumour, elimination of the products of disintegration, and building up of healthy tissue Wintz attributed the first of these entirely to the "destructive momentum"—namely, x rays elimination, etc, depended on the general biological condition of the whole body

In dealing with a patient sent for x-ray treatment, the first thing was verification of the diagnosis, but there was a valid objection to test-excision or curetting if avoidable Then the general condition of the patient must be considered The size of the tumour was important, first, on account of the possible difficulty of producing a lethal effect upon all parts of it, and secondly, on account of the general reaction which might result from the destruction of a large growth, raising the question whether the body was equal to the strain of elimination and recuperation Further inquiries should include metastases, the blood, the excretory functions, previous illnesses, the skin, especially as regards former irradiations or applications capable of producing irritation or secondary irradiation The possibility of adhesions fixing coils of intestine within the area of irradiation was very important, also any inflammatory state of the intestine or bladder Close collaboration was, therefore, necessary between the medical attendant, radiologist, and surgeon The preparation of the patient for irradiation should include rest, effective emptying of the bowels, and regulation of diet Some abdominal and pelvic cases were

irradiated fasting An injection of heroin or morphine and scopolamine was sometimes necessary With regard to general considerations of irradiation, the object was to apply to the whole of the diseased area a dose of x rays suitable for the destruction of the vitality of the malignant cells without serious injury to the skin and normal tissues This was generally more easily done in the case of deeply situated tumours than in the case of those on the surface When the tumour was on the surface it was more difficult to get sufficient dosage without injury to the skin The total time required for the irradiation might be several hours, and it was often necessary to have intervals bearing in mind that the dose was to be completed within about two days all possible provision must be made for the patient's comfort, and for the protection of those parts not being intentionally irradiated

After-treatment was as important as irradiation since, after the destruction of the vitality of the malignant growth, reparation of injured healthy tissue, elimination of products of disintegration, sustaining of the body against malignant disease, and restoration of healthy tissue had all to be undertaken These depended mainly on the condition of the body, but rest diet, fresh air attention to excretion and suitable diet were all of assistance Wherever local irradiation had caused local lowering of vitality, the tissue or organ affected must have rest and be protected from all irritation X ray sickness was generally lessened by regulation of the bowels before irradiation and the administration of a hypnotic Injury to the blood depended directly upon the quantity of rays absorbed and generally righted itself in about six weeks recovery should be helped by medicinal treatment, fresh air and sunlight For elimination of the products of disintegration and the restoration of healthy tissue they had to depend upon the resistance of the body and upon general care and treatment X-ray therapy for carcinoma might seem a formidable proceeding, but carcinoma was a formidable disease, and therefore justified some risks being taken

At the commencement of the meeting Dr W B Prowse showed two cases treated by x rays (1) sarcoma of the back (2) carcinoma of the breast Dr A W Williams also showed two cases (1) a severe case of lupus vulgaris of nose and upper lip cured by carbon arc light baths (2) lupus vulgaris of nose cheek, lip buccal mucosa, and larynx treated by sunlight baths and ecrin

TREATMENT OF SPASTIC PARAPLEGIA

A clinical meeting of the Aberdeen Medico-Chirurgical Society was held on November 6th, the President Dr G M Duncan in the chair

Mr A Mitchell showed two children with spastic paraplegia treated by Stoffel's operation He pointed out that small degrees of deformity might be treated by continuous fixation followed by general rhythmic exercise, preferably to music Intermittent forcible passive movements and massage should be forbidden, since the spasticity was usually increased by these measures More severe cases must be treated by operation, with the aim of enabling the patients to walk The main types of operation were three—resection of the posterior nerve roots section and suture of a main nerve trunk such as the sciatic and resection of portions of certain motor nerves in order to restore the muscular balance Such motor nerve were the branches of the obturator nerve and the nerves to the gastrocnemius and the soleus, occasional tenotomy of the adductors in addition was required This third method had been employed in the cases shown and both patients were now able to walk and to attend school

Mr W Anderson discussing these cases referred to the recent work in Australia of Hunter and Royle who advised division of the second third, and fourth rami communicantes of the sympathetics Mr Anderson had seen four patients treated by this method, but thought them still rather spastic

Dr W Brown showed a child of 23 months with tuberculous peritonitis, dactylitis, and lupus verrucosus The abdominal condition had been treated by operation followed by mercurial inunction and was now greatly improved He also showed a child of 14 weeks with congenital heart disease

Mr F K Smith referred to the rarity of tuberculous dactylitis in adults and asked whether the patients generally died in childhood

Dr G Rose confirmed the rarity of this condition from his examination of all school children of 13 years in Aberdeen for the last fifteen years Dr Brown agreed and said that in his experience such cases were almost always subjects of a multiple tuberculous infection and did not live long

Mr Andrew Fowler showed two cases of severe bilateral Dupuytren's contracture in adult males treated by multiple subcutaneous fasciotomy under local anaesthesia The cases were discussed by Mr F K Smith who suggested that as the fingers were now extended the palmar fascia might be excised to prevent the possibility of recurrence, Mr G H Colt, Dr H R Sopper, who referred to a good result obtained by Gill's operation—excision of the palmar fascia through a transverse incision and the implantation of a fat-fascial graft, Mr W Anderson Mr A Mitchell and Dr Cruickshank, who raised the possibility of treatment by radium on the analogy of its success in cases of keloid

Mr F K Smith then showed skiagrams of two cases The first was a tumour of the upper end of the femur in a man of 51 with a fracture of the femoral neck as the result of a slight accident in June, 1923 Tissue removed by exploratory operation at that time was reported as "ossifying chondroma" Operation was not considered advisable, and the patient did not report again till recently when definite changes for the worse were seen on skiagraphy This case was discussed by several members, and the general impression was that the tumour had now taken on sarcomatous changes, and that radium was the only possible method of treatment The second case was one of a girl of 17 with pyuria and some slight tenderness and enlargement of the right kidney Full examination by clinical and bacteriological methods—ureteral catheterization and cystoscopy x rays and pyelograms—showed irregular dilatation of the right ureter a pyonephrotic right kidney, calcareous deposits in the mesentery, and an oval calculus in the lower end of the left ureter, with dilatation and septic changes of the left kidney pelvis Tuberculosis had not been found This case was discussed by Dr Innes, Mr A Mitchell who suggested lavage of the renal pelves Dr Robert Bruce and Dr Cruickshank Mr Smith, in reply, stated that his proposed treatment was to estimate the separate functional activity of each kidney by the administration of urea and ureteric catheterization, to remove the calculus, and then to treat on medical lines In his opinion if the case were tuberculous there would have been signs in the bladder or at the orifices of the ureters by the time the disease in the kidneys had reached its present stage

PELVIC PAIN

A meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held on October 31st when the President Dr Louis Cassidy read an address on pelvic pain

Dr Cassidy said that pain was one of the common symptoms which brought a woman to consult a gynaecologist The most fatal diseases in gynaecology such as cancer were generally associated with pain only in the later stages when pain made its appearance the case was generally inoperable The most common cause of pain in gynaecology was of abdominal origin The pelvic and abdominal organs were insensitive but affections of the parietal peritoneum were appreciated by the patient as pain There were in the viscera no sensory nerves—a point thoroughly established by animal experiments Pain affecting these regions was referred pain the result of an affection of the parietal peritoneum The task of localizing pain in the pelvis presented many difficulties Some help might be obtained from a rough topographical outline of the abdomen a horizontal line being drawn through the umbilicus and a perpendicular one at right angles to the

Pain in the middle line, below the umbilicus, was generally associated with a lesion of the uterus or the bladder. Pain on either side of the middle line would probably be referable to the adnexa. The appendix also gave rise to many atypical symptoms. The hernial openings should always be palpated when a woman was in the erect position. Umbilical hernia might sometimes be the cause of pain. In abdominal pain in virgins it was wise to think first of the appendix, and in such cases rectal examination should never be omitted. A condition sometimes simulating acute appendix was the rupture of the Graafian follicle in the menstrual period. Pain proceeding from the kidney or ureter rendered the ureter in its vaginal course peculiarly sensitive to pain. According to some authorities left-sided pain was due to a varicose condition of the veins of the pampiniform plexus, which condition might be exceedingly difficult to diagnose. Left-sided pain was also often caused by an affection of the colon. Sacral pain, a common affection in women, had very little to do with an affection of the genital organs, and rheumatic conditions were often responsible. Therapeutic measures must be based on accurate diagnosis, the general health of the patient was related to her appreciation of the intensity of the pain.

Mr. Seton Pringle was not sure of the utility in diagnosis of the so-called areas of referred pain in visceral disease. Left-sided pelvic pain was commonly associated with stasis, it was increased by constipation and during the menstrual period. He associated this pain with the occurrence of Lane's sigmoid kink, though in his experience many cases were not relieved by correction of this congenital abnormality. He mentioned four cases of patients suffering from acute pain in the right iliac fossa associated with vomiting, slight rise of pulse rate, and some increased tension low down in the right iliac fossa, but without any rise of temperature or definite rigidity. On operation a rupture of a large Graafian follicle was found, a few drachms of blood having escaped into the pelvis. He found it difficult to reconcile the acute condition produced by this slight haemorrhage with the very slight reaction commonly caused by an accumulation of pus in the same locality.

Dr. A. R. Parsons mentioned the case of a woman complaining of pain in the right iliac fossa. He treated her for a time, and she was also seen by a surgeon, but as she was not improving she was, after examination, told that she was suffering from congestion of the ovaries, and treatment was recommended, but this also did no good, so she then consulted another gynaecologist. In the course of an exploratory laparotomy an abscess was found in the right ovary with an adherent appendix. Complete hysterectomy was performed, and the patient recovered.

Dr. Bethel Solomons said that the rules for diagnosis according to the position of the pain in the abdomen as suggested by the lecturer were not applicable to practice. In the diagnosis of gynaecological pain a careful bimanual examination with other diagnostic methods was usually more valuable than localizing the site of the pain. The amount of pathological change present did not in any way correspond to the degree of suffering. A woman with a large tumour or tuberculous tubes might have no pain, while some slight ovaritis or inflammatory band was productive of much pain. Whilst it was true that pain in the lower abdomen was not always gynaecological, it was also true that pain away from this region was often gynaecological. A striking instance of this was sciatica, and curable sciatica which had been cured in some instances by a subperitoneal Gilliam's operation, in others by removal of myomas. He added that this showed clearly that the presence of adhesions was not a necessary factor in pain. Pain on the left side was often due to a thickened ovarian cortex; this was relieved sometimes by resection of the ovary with removal of small cysts, in others by scraping the cortex. Pain on the right side, when referred to the ovary—especially when the latter was bound down to the broad ligament and was haemorrhagic—was often caused by an endometrioma. His practice was to remove the appendix if it was obviously inflammatory, if there was any pelvic peritonitis, or if the patient lived far away from a doctor.

Dr. A. K. Henry said that in appendix cases it was generally found that the first pain complained of was pain round the umbilicus. Pain was felt here before it was felt in the right iliac fossa, and if this was not so it was very likely that at operation appendicitis would not be found at all. He had seen cases in which the appendix almost formed part of the wall of either the caecum or the colon.

Sir William Smyly said that dysmenorrhoea was a form of pain which gynaecologists came across almost more than any other. Regarding the difficulty of diagnosis between appendicitis and inflammatory disease of the right tube, he had often found both present together, sometimes the origin of the disease was in one and sometimes in the other. In some cases a little blood in the peritoneum caused great pain, but in others it caused no pain at all. Matthews Duncan had said that retroversions which caused no symptoms required no treatment, and he divided retroversions into those with descent and those without. Sir William Smyly thought there was much less pain at the menstrual period nowadays than formerly, and this was probably accounted for by the fact that girls now led a more healthy life.

ENCEPHALITIS LETHARGICA.

At a meeting of the Medical Society of London on November 10th, Dr. F. M. Callander (the President) occupying the chair, a discussion on encephalitis lethargica was opened by Dr. F. Farquhar Buzzard. Dr. Buzzard's paper is printed in full at page 937.

Professor A. J. Hall gave an account of the epidemic of this disease during the present year as it was encountered in Sheffield and the surrounding district. Up to October there had been notified in the city itself 320 cases of encephalitis, and the notifications in the new *neighbourhood* would bring that figure up to about *500. During* the winter 1923-24 there had been one or two sporadic cases, and the storm burst with great fury about the second week of March. Many of the cases were very acute, and during April the fatalities were very high, the cases were chiefly of the restless, choreiform type. Taken on the whole, however, the mortality for the district had been surprisingly low—namely, about 10 per cent.—in contrast to 20 per cent. for the country generally. A great variation in type was noticeable, and many cases of abdominal myoclonus were seen, some of them so pronounced as to be admitted under a surgeon at hospital as abdominal emergencies. He discussed in some detail cases of polypnoea, and showed tracings of the breathing during attacks. He suggested that all cases showing this symptom should be notified. Hiccup was often a severe symptom.

Professor J. McIntosh discussed the etiology of the disease. Originally it was regarded as some form of cerebral poliomyelitis, while a few considered it an aberrant form of influenza. A good deal of animal inoculation had been done, but the monkey proved not to be a susceptible animal, although in one or two instances the disease has been communicated to it. Rabbits were easy subjects. It was shown that filtrates from the emulsions of infected brains were able to pass the Berkefeld filter and cause the disease in the inoculated animal. He was convinced that this disease was a distinct entity, and that it differed from all other neurotrophic diseases. He gave his reasons for separating it from herpes febrilis and from the spontaneous encephalitis of rabbits. He also urged a continuance of experimental researches to settle a number of points which were not yet very definite.

Dr. Salusbury MacNalty spoke on the epidemiological side of the subject, and referred first to the outbreak in London in the spring of 1918, when 55 persons were known to have had the disease. It was made compulsorily notifiable in this country in January, 1919, and early in that year there was a recrudescence, 41 cases being notified in one week early in February. The epidemic of this year was first localized in Lincolnshire. The total number of cases notified in England and Wales in 1924 (to October 25th) was 4,605, as against 1,025 in 1923 and 454 in 1922. The only method of spread seemed to be from case to case.

and not by the intervention of flies or any biting insects, nor by contamination of food or water

The PRESIDENT, in throwing open the meeting to general discussion, mentioned that, reflecting on the symptoms found in several patients in 1888, he was led to believe that they must have had this disease, and probably afterwards became ambulatory cases

Dr A W M ELLIS spoke of finding in the urine in cases of this disease a very largely increased quantity of ammonia and practically an absence of phosphoric acid In addition there was some albumose, showing intestinal and probably liver involvement

Dr C P SYMONDS spoke of the presence of the Argyll Robertson pupil in a number of these cases With regard to the distressing insomnia in many of the subjects of the disease, he questioned whether it was wise to attempt, by regimen and hypnotics to restore the normal rhythm in these patients His experience was that this was regained naturally in time

Sir WILLIAM WILLCOX thought that many cases of the disease escaped recognition because of the slightness of the symptoms, which were not carefully watched for In most cases there was a quick pulse, but in one case—a boy—it was only 50 per minute He inquired as to the significance of paralysis of accommodation in these patients, and whether Dr Farquhar Buzzard's experience agreed with his own that the prognosis was definitely worse in people over 55 or 60 years of age

Dr FARQUHAR BUZZARD in reply paid a tribute to the work done on the subject by Professor Hall in Sheffield In a public school where there was a small epidemic of mild cases four form masters had such severe and continuous hiccup that they had to absent themselves from school until it subsided When the pulse was abnormally slow the patient had usually reached a considerable degree of lethargy, probably on account of increased intracranial pressure Paralysis of accommodation and difficulty of convergence were very common in the disease He agreed with Sir William Willcox in regard to prognosis in older patients The gastro-intestinal symptoms present in some cases seemed to indicate that this might prove one route for the virus to the central nervous system He doubted whether treatment directed to the insomnia had much influence in altering the rhythm With greater experience the profession, he thought, would recognize cases more readily and there was thus hope for a steady decrease of the disease

"THE MEDICAL WITNESS"

At a meeting of the Hunterian Society held at the Cutlers Hall in the City of London, on November 17th a discussion, to which some eminent lawyers contributed, took place on the subject of "The medical witness" Mr H W CARSON occupied the chair

Sir THOMAS HORRIDGE, speaking as one of His Majesty's judges said that it would be difficult to exaggerate the importance of the medical witness In criminal trials from the simplest assault up to murder, the medical witness had not only to testify to the facts of the case, but frequently to give an opinion as to the criminal's responsibility In will disputes the case often turned upon the evidence of the doctor In nullity suits, again the evidence given by the doctor was of first importance In workmen's compensation cases the medical referee might himself be said to take part in adjudication and in a vast number of civil cases medical witnesses were called on one side or the other In preparing his evidence the medical witness should be careful to notice every minute fact even if it appeared at the time unimportant He emphasized the danger of approaching a case with a preconceived idea and determining whether the facts of the case fitted in with the theory the proper way was first to discover the facts and then form an opinion Even after the opinion was formed the mind of the witness should remain open so that the opinion might be remoulded in consequence of other facts elicited in the course of the hearing In the witness-box the medical witness should be on guard against the double question It was the habit of counsel to put to witnesses a double question with the object of eliciting a simple affirmative or negative as the case might be, and subsequently to use the answer as applying to that part of the question which suited counsel best If a witness could give a direct answer he should do so, any judge would allow him to qualify it afterward He would also warn witnesses against being lured into answering questions about circumstances of which they knew nothing or matters which they had not considered The witness should also use, as far as possible ordinary non-technical language It technical terms were used judge or counsel had generally to explain their meaning to the jury It was better to say that a man was badly bruised than to say that he was suffering from ecchymosis

Finally Mr Justice Horridge said a few words on the subject of professional privilege This had been granted to solicitors only because it was necessary for the administration of justice that there should be absolute confidence between parties and their legal advisers Even here the privilege was not unlimited, and in a case of criminal conspiracy professional communications had to be disclosed. Privilege was also allowed as between husbands and wives, although in recent years various Acts of Parliament had made husbands and wives eligible witnesses against one another On what ground was privilege claimed for the medical profession? He could see no ground except that of confidential relationship, and here where was the line to be drawn? If the doctor was to be privileged, why not the nurse or the chemist who made up the prescription Was the privilege to be extended to faith-healers and bone-setters and others who equally had confidential relations with their clients? Two Acts of Parliament—those dealing with the notification of diseases and the notification of births—compelled the doctor to reveal publicly matters which had come to him in his professional capacity, and he believed these Acts were passed with the support of the profession The evidence of doctors was required in order to assist the administration of justice, and he thought that doctors must know in their conscience that they had no claim to privilege, although they had a claim to protection, which was accorded them

Sir WILLIAM WILLCOX repeated some of the advice to witnesses which Mr Justice Horridge had already given In preparing his evidence the medical man should note and record everything that might have a medico-legal bearing The trial itself might prove to hinge upon a detail at first considered trifling The medical expert witness should not be *ex parte* and he should be free from bias this was of supreme importance in criminal cases He should refresh his memory by careful study of scientific literature, and if necessary should conduct scientific investigations to elucidate difficult points He should put himself in the position of cross-examining counsel and judge In a written report he should give his opinion and the reasons for it concisely, and the opinion expressed in such a report should be unalterable no doubtful expression should be put down there In the witness-box a direct answer should be given whenever possible and when not possible the reason should be clearly stated Evasions created a bad impression and lengthy explanations were apt to weaken the evidence If a compound question were asked the witness would be well advised to ask that it might be divided and put in sections If a book were cited the witness should ask to be provided with a copy and often if this were done it would be found that cross-examining counsel had taken an isolated passage to support his case whereas the main argument of the book supported the contention of the witness The expert witness unlike the common witness should remain in court during the whole of the proceedings this, indeed was legally allowed if not legally required

Sir FRANCIS NEWBOLT K.C. said that his own experiences with expert witnesses had been chiefly along another—a non-medical—line but such experience as he had had of medical witnesses had caused him to admire their fundamental honesty There was not usually among them that wide divergence frequently found in expert testimony or any testimony which indicated something beyond a mere difference of opinion He could assure medical witnesses that if they knew their book and were not carried away they could not be put down nor shaken in cross-examination I was well over

them to bear in mind that they must appeal to the common sense of the tribunal, and he thought it would be a good plan for them, in order to avoid bias, to imagine themselves as appearing for both sides in an action

Sir Bernard Spilsbury remarked that to those in court the responsibility upon a medical witness, whose word might decide the fate of an individual, must appear overwhelming, but he was not sure that the medical witness, even in a great criminal trial, felt quite the same himself Speaking in his own behalf, in his character of witness he was always impersonal He was not necessarily giving evidence against the prisoner in the dock, but against the person who committed the crime, and the identity of that person with the prisoner had to be proved by other means He went on to describe the care with which a medical witness should pursue his *post-mortem* or other investigations It was often forgotten that an expert had not merely to collect his facts, but to analyse and interpret them In almost all criminal cases it was essential that naked-eye observation of a dead body should be supplemented by the microscope, and he felt strongly that a pathologist or other skilled expert assistance should be available almost invariably for the general practitioner Before the medical witness gave his evidence in the first court—the coroner's court—he should have time and opportunity to weigh the facts he had elicited and compare them with facts in similar cases, consulting textbooks and other authorities as required The textbook, however, should only be supplementary, for many of the cases referred to in textbooks were based on evidence of somewhat doubtful value, and in any event the cases were decided at a time when medical knowledge had not made its recent advances

Dr Lewis Smith, from his experience of the coroner's court, added his testimony to the usefulness of the medical witness, and said that in some cases it became the duty of the coroner to protect the medical witness from censure by the jury One jury actually censured a medical witness because he had refused to attend another person who happened to be in the house at the time he was attending the deceased person What was more, the witness meekly accepted the censure, and the coroner failed to intervene and protect the witness

Mr Leigh Palmer added a few words from the point of view of a solicitor practising in the police courts The medical witnesses with whom he had largely to do were police surgeons, and he was inclined to complain that a good many of them did not give a long enough examination to persons accused of drunkenness, and in particular that they did not examine such persons for illness

Dr P B Spriggs as a police divisional surgeon, gave an account of the methods of examination he followed in the case of persons accused of drunkenness He also described the difficulties of the police surgeon in certain other cases, such as alleged indecent assaults, where as a rule there was no corroborative evidence He wished to make it plain that the police surgeon was returned, not on behalf of the police, but on behalf of the public The police surgeons worked with the police, but their evidence had to be, as the evidence of all medical men should be, entirely unbiased

---

A meeting of the Royal Medico Chirurgical Society of Glasgow was held on November 7th, when a lecture, including a lantern demonstration, was given by Professor John H Teacher, M D, on the implantation of the human ovum and the early development of the placenta The demonstration consisted of (*a*) lantern slides of a new ovum (Teacher Bryce No 2), (*b*) new slides of the original Teacher Bryce ovum, (*c*) slides illustrating the comparative embryology of the early stages, (*d*) theoretical scheme of human implantation Pictures by Mr A K Maxwell of both ova and of sections of the ovum —Teacher Bryce No 2—were also shown The material has been published in detail in the *Journal of Obstetrics and Gynaecology of the British Empire*, vol 31, No 2 July, 1924 The principal points dealt with were (1) The closure of the decidua capsularis by union of the uterine epithelium with a structure composed of the ectoderm of the ovum To this the name 'operculum' (German *Verschluss*) has been given (2) The relations between the maternal blood vessels and the ovum in the earliest stages (3) Theoretical considerations related to the nutrition of the ovum prior to implantation and the process of implantation itself

Reviews.

PEDIATRICS

Dr G F Still's *Common Disorders and Diseases of Childhood*,[1] which first appeared in 1909, now gives fresh evidence of its vitality by the appearance of a fourth edition In successive editions new chapters have been added, but the general character and plan of the book have remained the same The title is a true description of the contents It is not a systematic and complete textbook of the diseases of early life its fifty-nine chapters deal with all the common and a few uncommon disorders of infants and young children, and deal with them largely from the individual experience of the author That personal experience is indeed supplemented by the views and observations of others, but the principal merit of the book is that it is the expression of Dr Still's mind on common or perplexing questions of daily practice His discussions are frequently illustrated by synopses of his own cases and by valuable series of statistics prepared from his hospital and private records There are many, perhaps too many, elaborate and complete treatises on diseases of children These systems or encyclopædias—vast aggregations of chemical, physiological, and clinical data—have their value as works of reference They can hardly be called books, but rather huge, well arranged scrap-books, which are consulted but seldom read and digested Dr Still's book is a genuine book, the product of his mind and experience its scope is designed to cover all the ordinary difficulties and problems of the practitioner, especially the difficulties of diagnosis and the practical details of treatment The call for a new edition shows that the book is still serving the needs of the time and, being made of the stuff of experience, it may well endure to a later age Survival in medical literature is as precarious as in any other kind of writing, but in the meanwhile we welcome the present edition as a characteristic and valuable example of British medical literature We should add that the book is furnished with a number of excellent illustrations

The little book on natural feeding of the child is the first of a series on food and hygiene by Dr Montessus of Nice The author has been a lifelong advocate of simpler and more natural habits in eating, and in this volume he deals with the diet of the infant and the child He begins with the infant, when the exclusive diet of milk is giving place to a more varied diet, making a broad division into an early period ending with the completion of the first dentition, and a second period of childhood subsequent to this The book is written in an ardent missionary spirit, and especially commends the use of bread made from 85 per cent flour, the liberal use of well boiled cereals, of ripe and cooked fruits, and of vegetables And this vigorous propaganda is accompanied by numerous recipes, so that the book is intended for the French housewife in her kitchen as well as for medical men

Examination of Children,[3] by Dr A Levinson deals largely with laboratory and to a less extent with clinical methods of examination The book is an expansion of a course of lectures given at the Northwestern University Medical School, Chicago After instruction in obtaining a case-history and in the ordinary physical examination of the child in bed, a descriptive list of instruments, utensils, and chemical agents is given, and the remainder of the book is devoted to the method and technique of their employment, with brief remarks upon their interpretation There are a number of illustrations of instruments, apparatus, and of various clinical procedures, on the whole these are disappointing The descriptions of many bacteriological methods are too curtailed to be of service With regard

to tubercle bacilli in sputum, nothing more is said than that 'only rarely does one find tubercle bacilli in children's sputum." Of the Binet-Semon intelligence test it is said that it is probably the best mentality test available," and the reader is given no account of what it is or how to apply it. The author's opinions of basal metabolism are given in six lines, and again neither a definition nor the technique is touched upon.

Professor BENDIX's book[1] on pediatrics is one that has secured a place in current German literature and has now reached its eighth edition. It deals with the subject in the ordinary systematic way. After an introduction dealing briefly with the physiology and hygiene of the healthy child, it proceeds in the usual order with the diseases of the newborn, with general diseases, digestive disorders, diseases of respiration, and so on. A complete survey of subjects is given although none are treated exhaustively, and some very briefly. It is naturally written for German readers and references to English literature are conspicuously absent. Thus in the account of rickets the venerable and famous name of Glisson is not mentioned and though infantile scurvy is repeatedly called Barlow's disease, no reference is given to Barlow's classical paper. The account of nervous diseases is fuller than is usual in German textbooks of diseases of children. The book as a whole is a reliable but not very interesting guide to the subject, it no doubt deserves the success it has obtained in Germany, and it has been translated into Italian, Russian, and Spanish.

ESSENTIALS OF ORAL SURGERY

THAT oral surgery is a recognized specialty in the United States of America, and that it merits recognition, is well shown by the volume on *Essentials of Oral Surgery*,[2] written jointly by Professor V. P. BLAIR of Washington University and Professor R. H. IVY of the University of Pennsylvania. Their object has been to embody in a book the subject matter taught to their undergraduate students. They have therefore omitted detail of all major surgical operations while paying great attention to the recognition of surgical conditions of the mouth and jaws.

> The dentist should understand the pathology and be competent in diagnosis of surgical lesions located in his field but without special training is not called upon to perform major surgical operation in this region. At the same time there are many less serious surgical procedures which come directly within the scope of the dentist and these receive more detailed attention in this book.

In the main the authors have restrained themselves within these limits, and where they appear to have transgressed as in the pages dealing with the surgical treatment of deformities of the jaws, the specialized and interesting nature of the subject makes ample excuse.

The first eight chapters are occupied by a description of the anatomy of the mouth, and of the essentials of general surgical pathology and technique. The anatomical details are excellent, but it reads rather curiously to English eyes to find a sort of synopsis of the possible surgical lesions incorporated in the description of each part. Pathology and technique are dealt with in such a way as to bring out prominently the important points in diagnosis and infection as applied to daily practice. We should have liked however more details than are given in the dozen lines devoted to subacute and chronic inflammation. The remainder of the book is devoted to surgical conditions and the wide range of subjects it includes bespeaks a clinical experience of perhaps unique character, and it is experience of which the authors have made good use. Dentists will be interested to note that the authors speak with restraint as to the value of root resection. In the clinic at the University of Pennsylvania about fifty root resections are performed each year but the authors have found it impossible to follow up the cases, and can only conclude that the procedure offers a chance of success in certain cases. Pyorrhoea, under the name "chronic suppurative pericementitis" is dealt with in a few pages. Such statements as "gingivitis caused by serumal calculus or injury is the most frequent forerunner" and "in any case there is sufficient inflammation of the gingivae to permit a pyogenic infection," seem to show that the authors take little account of "sepsis" as the *fons et origo* of pyorrhoea, and it may be noted here that there is no mention of "septic" infection as a cause of leucoplakia. Both dentists and oral specialists will probably find their greatest interest in the pages devoted to the surgical treatment of deformities of the lower jaw. The authors have treated both retracted and protruded mandibles by surgical means and judging by their illustrations, with no small success. The operation described for retracted mandible would seem necessarily to involve section of both inferior dental artery and nerve by the Gigli wire saw, but no mention is made of ill results.

The book is well written, but there are a few lapses as on page 439 where the reader is warned that certain tumours "should not be incised with impunity." The illustrations are generally good and well chosen, but we have to confess to being unable to decipher some of the skiagram figures—for example that on page 402.

This volume will be a valuable addition to all medical and dental libraries, and the authors are to be congratulated on the results of their labours.

MODERN MEDICAL MONOGRAPHS

A SERIES of books is being edited by Dr HUGH MACLEAN entitled "Modern Medical Monographs." Each book concerns itself with a different branch of medical science and is written to provide the general practitioner with a short account of the modern point of view. In his general introduction to the series Dr. MacLean explains how the change from empirical to more scientific medicine must naturally be accompanied by changes in our conception of various diseases and their treatment. To keep abreast with these changes is a strenuous exercise even for the specialist, for the general practitioner and medical man of other specialties the task is impossible and they must be content to receive information sifted and epitomized. From books such as those of this series medical practitioners requiring enlightenment on one particular subject will be able to obtain it without a long search.

The first of the series is by Lieut.-Colonel L. W. HARRISON and entitled *Modern Diagnosis and Treatment of Syphilis Chancroid, and Gonorrhoea*.[4] This is a handy volume of some 160 pages, written by an admitted authority on venereal disease. It deals with the clinical diagnosis prevention and treatment of syphilis including a useful chapter on the general management of syphilis the general principles of treatment of gonorrhoea are clearly presented and modern methods of treatment lucidly described.

The second of the series *Modern Views on the Toxaemia of Pregnancy*[5] has been written by Drs. O. L. V. DE WESSELOW and J. M. WYATT. Concerning the subject of the toxaemias of pregnancy the medical profession waits expectantly for further knowledge for there are few pathological states of which we are more ignorant. Hyperemesis gravidarum eclampsia and nephritic toxaemia are constantly recurring problems to the practitioner. A clear-cut statement of the pathology of the toxaemias of pregnancy is impossible at present but the authors have succeeded in collecting together and presenting in a readable form the more important facts gained from recent scientific research and this book will certainly afford some guidance in the management of difficult cases.

The third of the series *Modern Methods in the Diagnosis and Treatment of Pulmonary Tuberculosis*[6] by

[2] *Essentials of Oral Surgery*. By Vilray Papin Blair, A.M., M.D., F.A.C.S., and Robert Henry Ivy, M.D., D.D.S., F.A.C.S. London: Henry Kimpton. 1923. (Med. 8vo. pp. 525. 350 figures. 32s. net.)

[3] *Modern Diagnosis and Treatment of Syphilis, Chancroid, and Gonorrhoea*. By L. W. Harrison, D.S.O., M.B., Ch.B., L.R.C.P.E., Lieut.-Colonel R.A.M.C., and R.H.P.(Retd.). (Demy 8vo. pp. viii + 160. 7 figures. 1 plate. 10s. 6d. net.)

[4] *Modern Views on the Toxaemias of Pregnancy*. By O. L. V. de Wesselow, M.B.Oxon., F.R.C.P., and J. M. Wyatt, M.B., B.Ch., L.R.C.P. (Demy 8vo. pp. viii + 92. 7s. 6d. net.)

[5] *Modern Methods in the Diagnosis and Treatment of Pulmonary Tuberculosis*. By R. C. Wingfield, M.B., M.R.C.P. Modern Medical Monographs, edited by Hugh MacLean, M.D., D.Sc. London: Constable and Co., Ltd. 1924. (Demy 8vo. pp. xi + 127. 5s. net.)

DR R C WINCKLER, is specifically dedicated to the general practitioner and senior student, tuberculosis specialists being warned that herein they will find nothing new, and the junior student that, though the book is simple, it is better that he should postpone reading it until he has completed the groundwork of his medical education The greater part of the book is devoted to the treatment of pulmonary tuberculosis—general, sanatorium, and specific One of the modern methods of treatment—namely, exposure to sunlight (as expounded by Dr Rollier)—might have received rather more notice in a book of this sort This useful little book is illustrated with some good a-ray photographs

CARBOHYDRATES AND GLUCOSIDES

A GREAT service has been done to readers of biochemistry in the series of monographs produced under the editorship of Professor Plimmer and Professor Hopkins Each monograph deals with a distinct subject of the study That entitled *The Carbohydrates and the Glucosides*, written by DR E F ARMSTRONG, is now presented as a fourth edition[9] Hardly any section of chemistry has been the subject of so much research with so little progress as the sugars Now at length the extensive work of Fischer, followed by that of Irvine and others, has led to the realization of a substantial knowledge of structural constitution among the carbohydrates In this realm of chemistry the influence of molecular structure presents an attractive subject of study There appears to be a promise of clearer information on the relation of carbohydrates to enzymes It is even suggested that the newly recognized molecular form of glucose termed the "gamma" oxide may be of critical importance in relation to diabetes Dr Armstrong's monograph affords an excellent survey of the subject The facts are brought into orderly arrangement The author shows how the members of the group termed carbohydrates are related to each other He describes the chemical transformations of which they are susceptible and the products of the reactions into which they enter He also gives a very full bibliography for the benefit of those directly interested in research on the subject What is presented in this volume would cost the reader an extravagant amount of time to gather for himself through the published researches

AMERICAN HOSPITAL POLICY

MACMILLANS of New York are publishing a series of volumes under the general title "Modern Hospital Library" Of these two volumes have come to hand One is entitled *First Steps in Organizing a Hospital*[10] which is written by MR JOSEPH J WEBER The work deals with the status of the hospital to-day, the hospital needs of the community, the best method of getting a hospital organization into being the duties and responsibilities of the trustees in the preliminary organization of the hospital, and the financing of the new hospital construction Great stress is laid upon the necessity of proper survey of the needs of the community before new hospitals are built There must be a thorough consideration of all the factors involved, including not only present necessities but also future demands, and there is the pertinent question, "Do the needs of the community warrant the establishment of an out-patient department?" The second volume, *Hospital Organization and Operation*,[11] is written by MR FRANK E CHAPMAN This is a very close review of the whole of the internal work of a hospital The principles of organization are considered, the administration, the medical staff, special diagnostic and therapeutic services, nursing, dietary social service, purchase of stores and their issue, housekeeping, repairs and maintenance, laundry, the out-patient department, and the relation of these ideals and principles to the operation of the small hospital The author in some parts of the work enters into rather too much detail, and there is a danger that such works may tend to stereotype internal administration too much, but the book is one that should be read by every medical superintendent and by those who are responsible for the administration of hospitals, for it is full of good ideas and information There are many illustrations and charts indicative of the methods of record of hospital case notes Both books are well got up, and bound in a clever imitation of leather

NOTES ON BOOKS

THE short guide to First Aid,[12] by G FORNI, is an excellent example of what such a work should be In his preface the author warns his readers not to expect first aid to be easy and pleasant, and urges them to read and re-read his little guide over and over again At the same time he disclaims all pretensions to popularize medical and scientific knowledge The advice which he constantly gives in cases for which first aid is a measure of temporary and urgent relief is to send for the doctor without delay The text of the book is clear and the illustrations admirable, especially those of bandaging, applications of improvised splints, and methods of carrying the injured There is a useful index

TWO American physicians have been at much pains to produce a series of graduated exercises useful for patients in different conditions of convalescence and health They point out very rightly that there have been many publications dealing with physical exercises, but that most of them have been written to exploit some cult or system, and are too often filled with incorrect or misleading statements, or they are compiled by inexperienced persons and are merely a jumble of exercises with no definite object, some, on the other hand, are carefully written textbooks by some well known authority, but too complex and technical for the ordinary reader DRS DICKSON and DIVELEY, in their little work, *Exercise for Health and Correction*,[13] have sought to produce a series of graded exercises—first for the convalescent who is still abed, and for this one there are a series of thirteen exercises, most of them quite simple and distinctly valuable, although the last of the series we are inclined to think somewhat too strenuous for a convalescent, then there follow a series of ten "setting up" exercises, and, finally, an extensive range of postural exercises which are suitable for all healthy persons The book is well planned, each exercise is set out plainly on one page, and facing the print is a reproduction of a photograph of the exercise being performed The photographs of the men are good, those of the women are ugly

MEDICAL AND SURGICAL APPLIANCES

An Apparatus for Estimating the Degree of Rotation in the Spinal Column

DR IDRIS T CARIAN writes Although many forms of apparatus have been made for estimating the degree of lateral curvature in the dorsal and lumbar regions of the spine, no satisfactory one has yet been produced for measuring the amount of rotation To meet this want I have designed a simple apparatus, as depicted in the illustration, named the 'spinal torsometer" It measures about 4 in by 2½ in, and can therefore easily be carried in the pocket It consists of an aluminium block, with a scale to record degrees above this is suspended a fine needle which immediately registers the angle at which the block is lying The subject to be examined is placed face downwards on a couch, a line is drawn with a dermograph through the tips of the spinous processes in the region desired, together with transverse lines to denote the middle of each such process The torsometer is placed transversely on the points of intersection of the line on successive vertebræ and the amount of rotation (if any) is read off (If, instead, it be placed longitudinally over each point of intersection the amount of antero-posterior curve can also be estimated) The apparatus can be obtained from Messrs Arnold and Sons (John Bell and Croyden Ltd), Wigmore Street W 1

British Medical Journal.

SATURDAY, NOVEMBER 22ND, 1924

MULE-SPINNERS CANCER.

It is difficult to realize that only two years ago the term mule spinners cancer was unknown seeing that at the present time it is almost as familiar to us as chimney sweeps cancer and yet very little has been written about it In a communication by Southam and Wilson which we published on November 18th 1922 attention was directed for the first time to the occurrence of epithelioma of the scrotum amongst the mule spinners of South Lancashire and the suggestion was put forward that this form of cancer was the result of the soiling of the clothes in the neighbourhood of the scrotum by lubricating oil from certain parts of the cotton spinning machinery The action of this oil on the scrotal skin prolonged over many years brought about epitheliomatous formation The clinical observation came at a very opportune time for mainly owing to the successful activities of the leaders of cancer research the importance of chronic irritation in the production of neoplasms was occupying the minds of the medical profession A few months previously at the Annual Meeting of the British Medical Association held at Glasgow Leitch had reported the experimental production in mice of malignant tumours—sarcoma as well as epithelioma—by the prolonged use of paraffin oils distilled from Scottish shales (the paper was printed in full in our issue of December 9th 1922) and thus had supplied a reasonable if not entirely conclusive basis for the suggestion of Southam and Wilson

It was not long before mule spinners cancer and its supposed cause were being discussed by those engaged in the cotton industry and by the technical and trades journals and investigated by the Government officials In some quarters it was denied that scrotal cancer was more prevalent amongst spinners than in the general population no comparative statistics were available and the hospital records showing that mule spinners had a preponderance of this cancer might have little significance in view of the fact that the clientele was drawn from a densely populated area where cotton manufacture was by far the chief industry Others while not denying this preponderance refused to believe that spinners were more subjected to the action of mineral oils than many other classes of workmen or that the lubricating oil had anything to do with the disease It was even suggested that injuries sustained in playing football were more likely to be the cause of the cancer Finally there were some who impressed by such clinical and experimental information as was then available attributed the cancer to the action of shale oils which were said to have been mixed with the petroleum oils Whether such an admixture was used or not is not definitely known for the composition of spindle oils is a trade secret These discussions were evidence of the interest aroused in industrial circles but the whole matter was taken out of the academic arena by the action of the principal trade union concerned and a test case was brought before the courts A workman aged 40 who had been engaged in mule spinning for many years, and had developed an epitheliomatous ulceration of the scrotum sued his employers for compensation under the section of the Workmen's Compensation Act dealing with epitheliomatous cancer or ulceration of the skin due to tar pitch, bitumen mineral oil or paraffin or any compound product or residue of any of these substances The case came on for trial in the Ashton County Court in January of this year, and expert evidence was cited on both sides Judgement was deferred

At page 941 will be found the paper on mule-spinners cancer read by Dr Archibald Leitch at the Annual Meeting of the British Medical Association held at Bradford in July last In it he discloses from unpublished figures of the Registrar General to which he had had access the surprising fact that 20 per cent or more of all the fatal cases of cancer of the scrotum occur amongst cotton spinners engaged in mule-spinning processes and he calculates that 1 in 2 000 die of the disease The liability he shows is less than amongst chimney sweeps although the total numbers are higher Continuing his previous experiments on mineral oils of the shale group he states that even refined oils of this class possess the carcinogenic property that certain crude petroleum oils are capable of inducing cancer, and that with a lubricating oil of the latter group he succeeded in producing malignant tumours The facts that he puts forward seem to leave little room for doubt that mule spinners are peculiarly liable to cancer of the scrotum and that it is caused by prolonged exposure to lubricating oil We understand that this evidence was not available in the law case to which we have referred and naturally could not have influenced the decision which was given on July 26th by Judge Mossop In his written judgement the learned judge found that the claimant had contracted cancer of the scrotum which declared itself when he was in the employment of the cotton mill, and that in the course of his work he was brought into contact with the fuller's shirt which caused constant friction in the neighbourhood of the scrotum further, his overalls especially in that region were frequently soiled with mineral oil which mineral oil was an irritant and it had been shown that cancer of the scrotum was common amongst mule spinners The conclusion is irresistible that there is a connexion between the disease and the employment The compensation claimed was awarded An appeal against this decision was entered but was subsequently withdrawn the Employers Federation accepting the ruling It was announced by the workers union the Amalgamated Association of Operative Cotton Spinners that they had a hundred cases on their books which would be affected by the decision It is a mystery why mule spinners cancer should have remained so long unrecognized It is said that the condition was apt to be concealed by the workmen as they feared that it would be diagnosed as syphilis and they would lose benefit

It is of interest to quote the following words from the quarterly report of the secretary of the trade union Mr H Boothman The resources of science and the great amount of research that is now being undertaken in various directions could we suggest find no worthier field in which to start than in the task of banishing the disease from all connexion with cotton spinning The trade itself in conjunction with the medical profession might investigate the cancer producing properties of mineral oil and direct their efforts to the production of an oil imperfect of such properties or at least in the provision or improvement of preventive measures It will be seen that Dr Leitch's independent investigations at the Cancer

Hospital Research Institute, London, have anticipated some of these suggestions There seems to be no reason why this form of cancer should not be entirely prevented, and probably a commission or committee composed of representatives of employers and workmen, together with technical experts and cancer investigators, would soon find effective means

THE PASSAGE OF FOOD THROUGH THE BOWEL

Our opinions as to the time occupied by food in passing through the bowel are based chiefly on the results of *x ray examinations of individuals who have eaten* some opaque substance such as bismuth, or on the time taken for some distinctive and easily recognizable foreign material, such as charcoal, to appear in the faeces From such studies it has been concluded that food reaches the caecum in four to five hours, in another four to five hours it has arrived at the splenic flexure, some sixteen hours are spent in the journey thence to the sigmoid flexure, through which the food is said to pass in about six hours The periods of time naturally vary under different conditions, but in general *it is assumed that food* taken by the mouth is completely evacuated through the anus in from twenty-four to forty eight hours But it may be argued against the evidence deduced from this type of experiment that it does not reveal what happens with ordinary food, since the test substance used is often bulky and always foreign, and is therefore likely to act as an irritant and to be hastened in its course through the bowel Apart from this aspect of the question, *it should not be assumed that* because the first elements of the test substance appear in the faeces in from twenty four to forty eight hours that therefore the whole mass is voided in this time

Dr W C Alvarez and Dr B L Priedlander[1] have recently found evidence, from some well planned and convincing experiments, that this is not the case They showed that patients after a barium meal continued to excrete barium in the faeces for many days, and that small glass beads, when taken with food, are often not all expelled for a week or more Their experiments *with barium* were very simple A number of healthy students were each given 60 grams of barium in milk, and the stools were collected daily for five days Weighed portions were incinerated and tested for barium It was found that from 40 to 80 per cent of the barium was expelled in twenty four to forty eight hours, and that extrusion of the remainder was slow, *lasting from four to five days* Thus we learn that even with a substance which probably passes through the bowel more rapidly than most food a considerable fraction remains within the alimentary tract for almost a week Their experiments with glass beads formed the major part of their work Fifty very small glass beads, about 2 mm in diameter, enclosed in a gelatin capsule, were given to volunteers at either *the morning or evening meal, and the stools* of these subjects were collected in large-mouthed jars and brought to the laboratory each day for examination and the search for beads *It is said of these beads* that, being chemically inert and mixing intimately with the food, they can have but *little influence on* intestinal motility, certainly no more than that of the many berry and fig seeds and bits of skin and fibre that are found so commonly in the stools By giving different coloured beads on each of three successive days it was possible to make three rate determinations on each subject of the test It may be *mentioned* that this appears to have been an extensive investigation The exact number of experiments is not recorded, but the authors speak of it as having been carried on, with some interruptions, for more than ten years, and all the four participators acknowledge complete agreement

Their conclusions, briefly, were as follows They found that ordinarily only some 15 per cent of the beads taken by the mouth could be found in the faeces on the first day, 40 per cent on the second, 15 per cent on the third, and 10 per cent on the fourth day Many days might elapse before all the beads were voided Thus, in one instance, the stools of a constipated person were sieved carefully until all the beads were accounted for, and the last one was not recovered until the fortieth day In some individuals the beads travelled more rapidly than in others, but it is instructive to note that a slow passage did not betray intestinal stasis, for no symptoms of disease were found in men and women who took a week or more to pass 70 per cent of the beads On the other hand, fast rates of passage, as indicated by *the recovery of 85 per cent of the beads* within twenty-four hours, were associated with the passage of soft, badly digested stools

We may conclude from such results as these that the colon normally retains food residues from meals taken during the preceding week or even earlier Ordinarily about 80 per cent of the residue from any one meal is extruded by *the end of the fourth day* the remainder has a more protracted sojourn Another lesson of considerable practical importance which seems to emerge from these investigations *with the* beads is that when the colon is well evacuated by a purge or through spontaneous defaecation no bowel movement should be expected or demanded the next day The conclusion, therefore, is that to give purgatives when the bowel is empty, either as the result of antecedent evacuation or because very little food has been taken, is to delay the return to habitual bowel movements

It was from a paper by T R Elliott and E Barclay Smith[2] that the authors gained the idea of studying the progress of food by means of glass beads Twenty years ago *Elliott* and Barclay Smith studied the distribution of food along the digestive tract by giving such beads to rabbits and *then killing* them at various periods The paper in which their results were published was entitled "Antiperistalsis and other muscular activities of the colon", it is a masterly survey of the physiology of movements of the colon With the help of these physiological observations, and other knowledge which has been gained during the intervening years, it is not difficult to find a plausible explanation for the fact that a considerable fraction of the food residue of a meal is retained in the colon for several days We know of three types of muscular movements in the colon—antiperistalsis, segmentation, and forward peristaltic movements Antiperistalsis, which results in a reversal of the main direction of passage, occurs chiefly in the ascending colon, its effect being to mix up the contents of the ascending colon and bring them into intimate contact with the walls of the bowel The periodic movements of segmentation result in division and redivision of the contents of the gut, and further favour mixing The slow forward peristaltic movements carry the mixed intestinal contents on towards the rectum We know that, forward from the hepatic flexure, the contents stiffen and become consolidated in the elongated

[1] *Journ of Amer Med Assoc* August 23rd 1924 p 576

[2] *Journ Physiol*, 31, 293, 1904

transverse, in the descending and iliac colon, churning movements are negligible, and the chief movement of these regions is a forward propulsive peristalsis In the ascending colon and cæcum the most intimate mixing takes place, and it is easy to understand how glass beads and other residues, become churned up with the new material arriving regularly through the ileo colic sphincter and how in this general shuffling of position particles may fail to be moved on in the sequence which their seniority deserves We venture to think that this explanation would be acceptable to Drs Alvarez and Freedlander who though they do not debate this question in detail, give an inkling of their views by remarking in picturesque language that food residues after leaving the ascending colon had gone the rest of the way to the anus like cars on a track'

These observations on the rate of progress of food residues through the bowel should provide material for reflection to exponents of the doctrines of intestinal stasis They point also to rational moderation in the use of laxatives

CELEBRATION OF THE SYDENHAM TERCENTENARY AT THE ROYAL COLLEGE OF PHYSICIANS

On Wednesday evening November 12th, a special meeting was held at the Royal College of Physicians of London to commemorate the tercentenary of the birth of Thomas Sydenham A considerable number of Fellows Members and guests was gathered in the large library of the College which had been arranged most tastefully for the accommodation of the visitors by the Treasurer, Dr Sidney Phillips Indeed, the beautiful proportions of the large library have never been seen to such advantage The guests were received by the President and at 9 o clock he delivered an address dealing with the life and work of Thomas Sydenham This address by Sir Humphry Rolleston, which has already appeared in the BRITISH MEDICAL JOURNAL (November 15th p 917), was admirable in point of style and delivery and was a model of what such addresses should be on an occasion when the work of a great medical name in the past has to be commemorated and reviewed To signalize the meeting various relics and other objects of interest connected with Sydenham were displayed for the inspection of the guests The fine portrait of Sydenham painted from life by Mary Beale was in the Censors' Room, and two other contemporary portraits—one by Closterman belonging to the College, and the other by a painter unknown, lent by the Wellcome History Museum—were placed on easels at the end of the large library On tables were displayed engraved portraits of many of Sydenham's friends and contemporaries and engravings of the College house in Sydenham s time The first editions of all his books were exhibited, and in some of them, on the title page was recorded the fact that it was given by the author In the subscription book of Fellows the signature of Sydenham was exposed and also the interesting document in the hand of Isaac Barrow, Vice-Chancellor, in which he certifies that Sydenham took his M D degree at Cambridge on May 18th, 1676 Sydenham's diploma from Cambridge as a doctor of medicine was also on view and his very valuable note book entitled 'Medical Observations" This note book of Sydenham does not form any complete medical work but is a book in which he recorded various medical observations and some of the passages in his various works can be traced to this source It is however doubtful if the whole is in his own hand though parts certainly were written by him The success of the celebration was considerable, it was a fitting tribute to the great work of one of the most distinguished men on the roll of the Royal College of Physicians

DIABETES INSULIN AND VITAMIN B

INSULIN is no more than a means for treating diabetes. If the incidence of the disease, and therefore the mortality ultimately due to it, are to be diminished, more must be learnt about the causes which bring it about The very multiplicity of suggestions is proof that we have no guiding principle Heredity, traumatic and other lesions of the nervous system, emotional shock anxiety mental strain, racial susceptibility over-consumption of starch and sugar, sedentary habits, the gouty diathesis obesity, and infection are factors any or several of which may be concerned, but we have no positive knowledge Since the discovery of insulin many investigators have concerned themselves with the problems of metabolism as well as of therapeutics which it has raised, but comparatively few with the factors which lead to the failure of the islands of Langerhans to discharge their functions efficiently The time has come to concentrate more attention on this aspect of the diabetes problem for however potent insulin may be in treatment it will not of itself suffice to arrest the increasing death rate The mortality is said to be increasing in America, and its great incidence in certain parts of India suggests the operation of some widespread influence in its causation Such an influence might well prove to be faulty diet In this connexion we are reminded of the effects upon the pancreas of a rice diet—that is to say, of a diet excessively rich in carbohydrates deficient in suitable protein in certain mineral essentials, and in vitamins A and B These faults are not peculiar to Indian diets but are to be found in others in common use in this country and America Such diets ultimately tend to atrophic changes in the pancreas, as was shown by McCarrison in our columns over five years ago[1] More recently Ogata has found that in birds fed on a rice diet the islands of Langerhans at first undergo hypertrophy showing an increased demand for the products of these cells The hypertrophy may be succeeded by atrophy if the diet be persisted in The atrophy, it is believed, is due in great part to want of vitamin B it is conspicuous we are told in the pancreas of fowls which have been given rice disease' (polyneuritis gallinarum) three times This raises the question whether chronic lack of vitamin B may not ultimately cause diabetes In Bengal McCay and his fellow workers have advanced good evidence for the opinion that the glycosuria so prevalent there among the leisured classes is due to the excessive ingestion of starch and sugar, combined with lack of exercise Since the amount of vitamin B needed is proportional to the quantity of carbohydrate eaten, it would seem likely that chronic deficiency of vitamin B is also a factor of importance in the production of the disease However this may be, further investigation of the causes which lead to failure in function of the islands of Langerhans is called for

GOLD TREATMENT OF TUBERCULOSIS

A SEMI EDITORIAL notice in *Ugeskrift for Laeger* for November 6th gives an interesting account of the meetings on October 28th and 29th of the Medical Society in Copenhagen The experimental work of Professor Moellgaard on cattle and other animals, and the clinical tests carried out in various tuberculosis institutions with sanocry in' (mentioned in our issue of November 8 h p 870) have aroused great interest during the past year in Denmark The Danish medical profession flocked to the meetings now only from Copenhagen but from all over the country in such numbers that the 'Domus Medica in which he lectures were to have been held, was found far too small, and Professor Faber's lecture room in the Pig ho pital had to be used Even so many of the audience had to remain standing for three to four hours at a time on both

[1] BRITISH JOURNAL OF EXPERIMENTAL PATHOLOGY, February 1921, vol 1 p 177
[2] *Rev de Médecine*, 1922, t 15.

days Professor Moellgaard gave an account of the special qualities of sanocrysin as a germicide *in vivo* It is said to be non-toxic for the tissues, easily diffused through the body, slowly excreted from it, and very toxic to the tubercle bacillus It is claimed that no reaction follows when it is introduced into the body by intravenous injection provided the tissues are healthy, but if they are tuberculous a violent reaction ensues, because (so it is supposed) the wholesale destruction of tubercle bacilli floods the body with their toxins By giving a serum as an antidote to this reaction Professor Moellgaard believes he has succeeded in greatly reducing its violence In support of his claims he gave an account of his treatment of animals accidentally or artificially infected with tuberculosis, and he reported two cases of tuberculous monkeys, emaciated and almost moribund, in which the lungs showed signs of extensive disease, and there was enlargement of the spleen, ascites, and ileo-caecal tuberculosis Complete clinical recovery was effected, the monkeys became lively again, and their weight increased by 50 per cent The clinicians who gave an account of their experiences with sanocrysin during the past year in hospital practice were Dr Secher of the Bispebjerg Hospital, Dr Wurtzen of the Öresunds Hospital, Professor Bie of the Blegdams Hospital, Professor Faber of the Rigshospital, Dr Gravesen of Vejlefjord Sanatorium, Dr Strandgaard of Boserup Sanatorium, and Dr Permin of the Frederiksberg Hospital It appeared from their reports that human beings as well as animals reacted to sanocrysin, after it had effected a clinical recovery, in the same manner as healthy animals which had never suffered from tuberculosis Tragedies as well as brilliant successes were recorded, and the errors of dosage responsible for the former were discussed The speakers who gave an account of their experiences with tuberculosis of the skin (Dr Tomholt), tuberculosis of the iris (Dr K K K Lundsgaard), and surgical tuberculosis (Dr Chievitz), were guarded in their attitude towards sanocrysin, but although Dr Chievitz had not obtained any outstanding results from the intravenous injection of sanocrysin in surgical tuberculosis, he had obtained complete local healing of tuberculous teno-synovitis by exposing the tuberculous structures and infiltrating them with the drug The speaker who was most reserved in his claims and most cautious in his forecasts of the efficacy of sanocrysin was Professor Moellgaard himself, and his attitude in this respect was the more appreciated since the experimental evidence he adduced was such as to tempt enthusiastic research workers to believe that *sterilisatio magna* had become something more than a mere possibility in tuberculosis It is stated that some of the papers read on this occasion may soon be published in *Ugeskrift for Laeger*

PREVENTIVE SURGERY AND THE CRIPPLE

Preventive medicine is a familiar term, preventive surgery possesses more novelty, but we may reckon as one part of it the prevention of deformity due to injury or disease There is some justification for the claim made by Dr C J Macalister in the new (second) number of the *Cripples' Journal*[1] that it may be dated from 1898, when Liverpool established its hospital for children at Heswall, on a fine site looking across the Dee to the mountains of North Wales, and Miss Hunt, with the assistance of Sir Robert Jones, started on a modest scale the home at Baschurch in Shropshire which has grown into so great an institution, and is the mother house of the large scheme now on foot for the benefit of cripples of all sorts It is true that, as Mr Muirhead Little recalls in the biography of his father, Dr W J Little, which he contributes to the same issue, the treatment of congenital deformities, club-foot in particular, had been begun more than half a century earlier, but surgeons were hampered by the fear of sepsis, and the treatment of tuberculosis of bones and joints had hardly been begun The plan of the larger scheme, to which we have referred on several previous occasions, is explained in the same issue of the *Cripples' Journal* by Mr G R Girdlestone, surgeon to the Wingfield Hospital for Cripples, which is situated near Oxford The general idea is to form areas to cover eventually the whole country each area would have a central orthopaedic hospital with a clinic in every fair-sized market town, "held on market day, so that the carriers and omnibuses may bring in the cripples with the market folk" The clinic is conveniently held in the cottage hospital where there is one, if not, in some place supplied by local initiative, or, when the interest of the local authority has been enlisted, in a room lent by it perhaps at the town welfare centre Usually the medical officer of health and the school medical officers are very ready to co-operate, and the scheme has only to be explained to them to secure the goodwill of the medical practitioners in the district Here, then, we have the regimental medical officers, the collecting stations and field hospitals, and the base hospital The place of the casualty clearing stations is taken by the general hospitals in the area These form "nodal points in the system and centres of consultation and co-operation" between the surgeons of the central orthopaedic hospital, who visit the local hospital periodically, and their medical and surgical colleagues Where such relations can be established they form "the best possible form of local orthopaedic clinic" The Wingfield Hospital has such relations with the general hospitals at Oxford, Reading, Aylesbury, and Windsor, each of which has a member of the staff of the Wingfield Orthopaedic Hospital working in its orthopaedic department The analogy with the military organization made familiar during the war is only rough, but it may serve Other things are wanted, such as seaside convalescent homes, especially for tuberculous cases, and the central orthopaedic hospital of the area had better be in the country How many areas have taken up the scheme we are not told, but we have no doubt that it will everywhere enjoy the support both of the medical profession and of the public It is being extended to Wales, and the Principality—as Sir John Lynn-Thomas points out in the same issue of the magazine from which we have quoted—starts with two advantages the Welsh National Memorial Association, founded by Major David Davies, M.P., in memory of King Edward, undertakes to treat surgical tuberculosis, and the Prince of Wales's Hospital, established during the war in Cardiff by the writer of the article for the treatment of crippled soldiers, is now being made available for the civilian population The demands upon it are so considerable that it is proposed to erect on a healthy site a subsidiary building affording another hundred cots, when provision can be made for the systematic education of the children in elementary knowledge Sir W de Courcy Wheeler, who has an article on the cripple in Ireland, sums up the general principle by which the promoters of the whole scheme are actuated in the following pithy sentences "It is futile to have special surgical skill without proper country accommodation It is more futile to have open-air homes for cripples without the special surgical and nursing skill which is essential to success"

MEDICAL CARE AT THE WEMBLEY EXHIBITION

Statistics are now available regarding the medical supervision of the British Empire Exhibition, during the course of which 17,403 173 visitors were admitted The St John Ambulance Brigade and the British Red Cross Society shared the responsibility for dealing with the 23,388 cases of illness which occurred About 400 of these were classed as serious cases, 124 being sent to the Willesden General

Hospital, the remainder by motor ambulance to their homes or elsewhere Ambulance cars were at work day and night throughout the period of the exhibition, and the mileage covered by them amounted to 10,625 The Stadium casualties of various kinds numbered 850 A medical officer and first-aid attendants were on duty in the arena and at the special ambulance station during all ceremonies and performances A portable *x* ray apparatus was specially procured for the rodeo performances, and was found very useful In our columns of May 24th (p 927) and August 9th (p 242) we described the systematic hygienic supervision of the whole exhibition, and it is satisfactory to note that the general health was very good The difficult problem of preserving the health of natives coming from climates very different from that of the summer of 1924 was satisfactorily solved

THE FUNCTION OF STATISTICAL METHOD

THERE are plenty of statistical textbooks and plenty of people who advise medical men and students to learn statistics In fact, the plan of the School of Hygiene, drawn up some years ago, made some provision for this science, applied science, or art—the learned differ as to the correct designation Short practical expositions of the utility of statistical methods are, however, less common, and the Fatigue Research Board has done well to publish Mr Udny Yule's lecture on the function of statistical method in scientific investigation[1] The claims Mr Yule makes on behalf of the, let us say, *method* of which he is so great a master are by no means excessive Some statisticians would dissent from the suggestion that even the most perfect experimental investigation can be fully appraised without recourse to a statistical method But even if the use of the statistical method is strictly confined within the limits Mr Yule suggests, there will be more than enough work for all the statisticians America can train or hire during the next hundred years Thus, Mr Yule writes "The expert in public health for example must take the records of deaths as they occur, and endeavour as best he can to interpret, say the varying incidence of death on different districts Clearly this is a very difficult matter The proportion of deaths to population in a district is affected not only by its sanitary condition—however broadly we interpret that term—but by all kinds of other circumstances not only by such definite circumstances as the age of the population (if there are many of the old this will tend to throw up the number of deaths) and the proportion of the sexes (age for age the mortality amongst women is usually less than amongst men) but also by that medley of circumstances which differentiates any chance sample of individuals from any other The purpose of *experiment* is to replace these highly complex tangles of causation which confront the unfortunate investigator who is limited to pure observation by quite simple systems in which only one causal circumstance is permitted to vary at a time When this is done the effects of changes in the one factor stand out clearly by themselves When it cannot be done, the effect of changes in the one factor is overlaid by the effects of all kinds of other causes, disturbing causes,' as they may be called for they are causes the operation of which we wish to exclude, and they disturb the simple effect of the one factor the influence of which we wish to note Statistical methods are methods for handling and elucidating the meaning of data affected in this way by disturbing causes,' or generally by a multiplicity of causes Hence their very wide applicability" Mr Yule demonstrates the utility of the method on a series of problems chosen from different fields He points out how certain algebraical results, which at first sight might seem of purely academic interest, are found to be of tools in seemingly unrelated practical researches Thus a result in statistical algebra first obtained by Poisson was employed (in two cases independently rediscovered) in a research on the emission of radio-active particles in a study of haemocytometric counts, in an investigation of industrial accidents and in a paper on the bacteriology of water Mr Yule conveys a great deal of information in an attractive style Although primarily intended for the field investigators of the Industrial Fatigue Research Board, this report deserves a wide circulation and should appeal to medical readers

THE GENERAL MEDICAL COUNCIL ELECTION

On November 10th a London surgeon Mr D C L Fitzwilliams, sent to a number of medical practitioners (we have no idea how many) a stencilled letter, beginning "Within the next few days there will be an election of four representatives on the General Medical Council I see that the B M A are putting up four panel practitioners As the whole of the profession is not panel, there is no reason why all our representatives should be panel doctors and therefore I am asking you to vote for—' Here follow the names, with brief commendations, of Dr R Fielding-Ould and Mr F H Westmacott, who are standing as independent candidates in the election of four direct representatives for England and Wales One of the recipients of this circular letter forwarded it on November 16th to the Medical Secretary of the British Medical Association, who wrote next day to Mr Fitzwilliams informing him that two of the Association's candidates are panel practitioners and two—Dr Bolam and Sir Jenner Verrall—are not Dr Cox added I suppose it is too late for you to undo the possible mischief you have done but one can only hope that the members of the profession generally have taken more trouble than you evidently have done to know what is going on in the medical world" Mr Fitzwilliams replied on November 18th that his attention had already been drawn to his error, which he only realized when he got the voting papers He added As I am afraid I have mixed up four gentlemen proposed by some other institute with the four that were being proposed by the B M A I am extremely sorry for my error, which I am afraid it is too late at the present moment to undo" The election will be over before this issue of the JOURNAL appears but we think it right to place the facts on record

THE next Australasian Medical Congress will be held in Dunedin, New Zealand early in 1927 under the presidency of Dr I E Barnett who is retiring from the professorship of surgery in the medical school of Otago University, Dunedin The general secretary of the Congress is Dr W P Gourland the associate secretary Professor A M Drennan, and the treasurer, Professor D W Carmalt-Jones

THE Secretary of State for the Colonies has appointed Sir William Prout C M G, O B E M B late Lieut.-Colonel P A M C, to be senior medical adviser to the Colonial Office in London, in succession to Sir John Poë Bradford resigned Dr A F Horn C M G has been appointed junior medical adviser, in succession to Sir William Prout

THE GENERAL ELECTION

THE result of the election for three representatives of the combined Scottish Universities in the House of Commons was announced on Thursday November 13th The figures were as follows

Sir Henry Craik K C B (C)	7 163
D M Cowan (L)	5 010
Sir George Berry F P C S Ed (C)	3 771
The Rt J M Munro (Lab)	1 623

NURSING OF MENTAL PATIENTS.

Suggestions for Reform

The Report of the Departmental Committee appointed by the Board of Control, with the approval of the Minister of Health, and presided over by Dr C Hubert Bond, to consider the nursing service in the county and borough mental hospitals, has recently been published.[1] A number of far-reaching recommendations are made, and the visiting committees are strongly urged to put them into effect at a very early date, because it is felt that an improvement in the nursing service lies at the foundation of advancement in mental treatment generally.

In spite of improvements in general conditions and considerable increases in wages, there is great difficulty in obtaining suitable probationer nurses in mental hospitals and though, under the ægis of the Medico-Psychological Association, much activity in teaching and training is in progress, the figures as to duration of service reveal the fact that a far too high proportion of the women entering the service neither realize its vocational nature nor seriously intend to undergo training. It is regarded by many merely as a temporary means of earning a living, rather than as a career. The problem before the Committee, therefore, was to discover how the nursing service in mental hospitals could be improved so as to attract the right kind of applicant, because, as the Committee fully realizes, high qualities of heart and mind are quite as essential in the nursing of mental disorder as in the nursing of any other form of illness.

The Committee considers that if the mental nurse is to take her rightful place in the nursing profession and obtain an *equal* status with the general trained nurse, the most complete training and facilities for passing examinations must be provided. It feels that to obtain applicants with a good secondary education is not so much a question of offering high initial salary as of providing really good training with fair living conditions, and the prospect of well paid responsible posts on attaining proficiency. To secure equality of opportunity and uniformity in the standard of training it is considered essential that no mental hospital should accept nurses for training unless it is able to afford proper facilities for the purpose.

It is suggested that mental hospitals should be divided into three grades for the purposes of training—namely, hospitals possessing the necessary facilities for the full curriculum in mental nursing; hospitals possessing the necessary facilities *for the final examination only*; and hospitals *not recognized* as training schools. In order to make this scheme effective organized co-operation between two or more mental hospitals is obviously necessary. Senior probationers from the full training school would have to be sent to hospitals of the *second grade to complete* their training, and hospitals in which no training is provided would have to be supplied with staff nurses from other centres.

The Committee points out that to carry out properly its recommendations they must be adopted generally throughout the country. In a sense they contemplate a national service in which the same qualifications are recognized and required at all institutions for the same positions, and in which promotions may be freely obtained from one institution to another. In addition to reciprocity between mental hospitals, great emphasis is given to the need of co-operation between mental and general hospitals, as it is only in this way that adequate facilities for training in general as well as mental nursing can be secured. Dr Bond and his colleagues think it of extreme importance that the facilities already existing in some places for seconding mental nurses to general hospitals should *become universal* and that authorities should encourage trained mental nurses to take a general nursing certificate. The hope is expressed that this procedure may be found practicable without any contravention of the Asylum Officers' Superannuation Act as to service, aggregation of service, and contributions. Should there be any doubt as to all or any of these matters it is thought that this should be remedied by legislation. Conversely, it is believed that with the establishment of training schools there will be an added inducement for general *trained nurses* to gain experience of mental disorders, and that some understanding of elementary psychology, both normal and morbid, will be found increasingly necessary in general nursing.

We believe the insistence in this report on the necessity for mental nurses being equipped with an adequate knowledge of general nursing principles to be thoroughly justified, for not only are the subjects of mental disorder liable to physical disease, but many forms of mental disorder are the outcome of bodily disturbances—intestinal toxæmia, influenza, tuberculosis, *encephalitis lethargica*, syphilis, alcoholism, puerperal states, and biological changes occurring at critical *periods of life*. Such cases require active medical treatment and the highest nursing skill. A confusional psychosis needs attention as unremitting and assiduous as that needed in a case of pneumonia, and the modern mental nurse should be in a position to understand the great responsibility which devolves upon her in dealing with such a case. It may not immediately be possible for a great number of nurses to obtain a double qualification, but a beginning might be made if the committee, superintendent, and matron of each *mental hospital endeavoured* to get in touch with the general hospital in the area served by their institution.

One of the guiding principles of the Departmental Committee is that it is fundamentally important to regard mental nursing, not as a *separate profession*, but as a branch *of the nursing profession*. If the scheme formulated in this report were put into operation the status of the mental nurse would certainly be greatly enhanced, and an important step would have been taken towards a more complete hospitalization of the mental hospitals. We feel that the success of this scheme, which aims to effect a radical transformation of the mental nursing service, is dependent in a large measure upon the part which mental hospitals are to play in relation to mental disorder as a whole. If these institutions are to be dissociated entirely from the early treatment movement so that they will deal with even fewer recoverable psychoses than at present, *it will be increasingly* difficult to attract the best *type of nurse or* medical officer.

Every credit is due to the nurses in mental hospitals who, with marked skill and devotion, care for the chronic and infirm patients with which its wards are chiefly filled. Without minimizing the *value of this good work*, it must be said that the true nursing spirit flourishes with difficulty in an atmosphere of chronicity. It is scarcely worth while to bring these institutions, at great expense, to a condition of the highest medical and nursing efficiency if they are only to deal with unrecoverable cases. There should be a constant influx of recoverable cases to infuse a spirit of hopefulness throughout the whole institution. If local authorities are empowered by law to make provision for early and recoverable cases without certification, the mental hospital staff should take their part in the treatment of these cases, whether they are treated in villas on the estate, in separate clinics, general hospitals, or in out patient departments. The mental hospital should be the administrative centre from which the various psychiatric activities of the district radiate. If such a policy is not pursued the mental hospital will be more than ever divorced from the community as a whole, and stagnation must be expected. If the nurses in these hospitals have nothing to look forward to but the exclusive care of chronic cases, it is difficult to imagine how the vision of a mental nursing service, such as is *outlined* in this report, can ever be realized.

The Committee is evidently of the opinion that more use will have to be made of the medical and nursing staff in mental work outside the hospital. It points out that the ascertainment and study of cases of mental illness and *mental defect* cover an immense field, and include school work, delinquency, indigence, various forms of institutional care, and the activities of welfare societies. At present these questions are dealt *with*, both centrally and locally, by different bodies, and the *Committee* feels that this leads to a loss of efficiency. The *suggestion* is made that the administration of all matters relating to mental health should be vested locally in one statutory committee of the county or county borough council which committee should be *in close touch* with the

[1] Board of Control. Report of Departmental Committee on Nursing in County and Borough Mental Hospitals. 1924. *H M Stationery* Office. 1s 3d net.

public health committee It is pointed out also that in organizing arrangements to meet the requirements of each area, much wider use could, with great advantage to the services be made of the expert staff—medical and nursing—of the mental hospitals serving that area If these suggestions were carried out a much more attractive career would be possible for the mental nurse than is at present offered, and there would be every inducement for educated persons to take up this work as a vocation

THE NEED FOR EXTENDED SICKNESS INSURANCE

ADDRESS BY LORD DAWSON OF PENN

At a meeting of the Insurance Institute of London (a body consisting of the officials of insurance companies) on November 17th, Lord Dawson of Penn, G C V O, M D, gave an address on the need for extended sickness insurance Mr G W REYNOLDS President of the Institute, was in the chair, and the theatre of the London Institution, in which the meeting was held, was crowded

Lord DAWSON explained that his proposals had no reference to the rich who could provide for themselves nor to the manual workers who were provided for by national health insurance he confined himself to the middle class—to people with an income below £1 200 a year For the benefit of this important class the provision for sickness needed revision and extension The public knew and cared much more about health than formerly but with the acceptance of a higher health standard went increased cost He instanced such conditions as persistent indigestion kidney trouble and chronic cough—conditions which formerly were allowed to drag on but for the investigation and efficient and timely treatment of which the means were now available But the means were costly investigation might in certain cases involve chemical analysis or x ray examination and the treatment might be an early operation The medicine of to day offered many more resources than the medicine of yesterday but the very excellence and complexity of the methods available involved the individual in a really burdensome cost

Certain social conditions also pointed in the same direction It was notorious that the normal life of the middle class was rendered arduous by the absence of domestic help The arrival of a baby was looked upon by a domestic staff as something of a grievance and there were few middle class houses in which a long illness could be tolerated The home as a place where illness could be treated must be supplemented by institutional provision Again the health of the individual was of fundamental interest to society Prompt and efficient treatment diminished the extent of the disability of the breadwinner and shortened the time for which that disability operated It would not be difficult to bring forward examples to show that people of moderate means had been handicapped in their careers for ten years or more owing to financial stringency following one serious illness in their family

What he had in mind was not some State provision which would involve State control Of all the professions there was none which would be more cramped in its development, more damaged in its finer growth than medicine under State control (Applause) The reason was not far to seek Over and above the technicalities of knowledge, there were certain harmonies of temperament which entered very largely into the relations of doctor and patient and anything which interfered with that confidence and so to speak voluntary allegiance, would diminish one of the best things this country possessed The problem of the State was to make sure that there was adequate organization and access to the best means of investigation and treatment of disease combined with a reasonable amount of freedom in the personal relationships involved The decisive middle class vote against socialism at the last election must not be held to mean a policy of *laissez faire* and the presence of Mr Neville Chamberlain at the Ministry of Health was an assurance that these problems would be approached with knowledge courage and sympathy (Applause)

Passing to the problems of organization involved in any extension of sickness insurance Lord Dawson said that one further provision of institutional aid would certainly be needed This would mean that cases were dealt with more economically as well as more efficiently although it would not involve necessarily a patient's stay in hospital The provision would include not only hospitals but clinics to which he could go at certain times for examination and treatment Towards this provision the middle class patient must contribute although the entire cost would be beyond his means Lord Dawson thought it would be a proper function of the local community to provide such clinics and hospitals Local communities were allowed to provide for education and to buy and administer land for recreational purposes why not also for the organization of health? In this connexion he referred to the recent developments at Bath, where the Combe Park hospital was operating, would be hoped stimulate other communities to make similar far sighted provision But with the setting up of these clinics and hospitals it was necessary to beware of certain dangers Local authorities were apt to favour the whole time service of a doctor Whole time officers were necessary in many cases but he would enter a caveat against any rash multiplication of them, for this would prove to be the slippery slope leading to the nationalization of medicine Moreover in such a nationalized services the patient would be separated from the doctor of his choice and from the general practitioner would be withdrawn the stimulus to his intellectual powers which he got from contact with all the illnesses of his patients It was upon the quality of the general practice in this country that the welfare of the community depended more than upon any other single factor

Lord Dawson next discussed the question of cost acknowledging himself in this field an amateur But it seemed evident to him that the cost of a serious illness could not be met out of a moderate income The obvious recourse was to insurance which was extending its bounds in many directions though not at all, or only very tentatively in security against illness He was well aware that any insurance scheme must be economically sound and that there would be a tendency for the less healthy to insure and for the more health to stand out this might be partly met by making the insurance cover all members of families There was also the big difficulty of administration and inspection To meet this he would suggest the formation of health societies in local communities such societies to act as a buffer between the insured and the insurance company The difficulty of a company in not knowing its liabilities might be met by fixing a maximum payment for any one year He was against the limitation of insurance to named illnesses because an insured person was then sure to have illnesses which were not on the schedule Nor was he in favour of a scheme of insurance already mooted in certain quarters solely against an operation But he was convinced that only by some measure of extended insurance could the problem be met unless indeed we were to drift into socialism as applied to medicine The organization might most favourably begin locally and at the periphery in some progressive community such as a garden city where the people formed a compact organization But he thought it would not be unreasonable for an insurance company to interest itself in some well thought out scheme with all due limitation of risk and incidentally a sickness insurance would introduce life business and reduce the claims under life policies

Sir ALFRED WATSON (Government Actuary) rejoiced that Lord Dawson had not in mind a further instalment of State insurance The modern tendency was to regard all things as possible to the State, but he hoped the day was long distant when the intimate and vitally important services rendered by the family attendant would be taken over by a State official possibly with penalties attached to the non-observance of his orders! As an actuary he found difficulty in defining a plan for a policy and rate of premium for such an insurance undertaking as Lord Dawson had in mind The continual improvement in medical science made it a still more difficult proposition for an insurance body to cover the liabilities of a person who wanted all these benefits More might be done on the lines of insurance against the loss of the breadwinner's income

Sir WALTER KINNEAR (Ministry of Health) was glad also that the proposals did not involve a State scheme although Lord Dawson had referred ominously to grants in aid The speaker was continually reminded of the limitations of the national health insurance system in spite of the fact that £1 000 000 a month was distributed in sickness benefit There was a large and growing body of the community for whom no properly organized sickness benefit existed He confessed that when he probed to the causes underlying the sickness brought to his notice in national health insurance administration he was impressed by the fact that a very large proportion of it was avoidable if only earlier attention had been forthcoming The were indebted to Lord Dawson for calling attention to this clamant public need though the speaker's experience in connexion with the national system made him cautious before pronouncing an opinion as to whether a comprehensive and ubiquitous scheme on the lines suggested was a feasible proposition

Lord DAWSON said in reply that he had never thought that insurance alone would solve the problem but that insurance should go hand in hand with some new public provision Imagination was needed to imagine Possibly his own professional instincts inclined him to let his imagination run too loose, while the professional instincts of those who addressing unduly restricted the range of their imagination But he thought that much could be achieved by a round table conference

THE FUTURE OF MEDICINE IN INDIA

Sir Gerald Giffard's Address

The grave and complicated problem of the future of medicine and the medical profession in India was discussed by Major-General Sir Gerald G Giffard, K C I E (I M S, ret), in a paper, of which the following is an abstract, read before the East India Association, at Caxton Hall, on November 17th

Sir Gerald Giffard introduced the subject by referring to some noticeable differences existing between the medical profession in Great Britain and that in India In India, medicine is practically a Government department Almost all the medical practitioners are or have been Government servants, the public health service is almost entirely a Government concern, and nearly all the medical schools and hospitals are Government institutes In the second place, in India the existence of inferior and imperfectly trained practitioners (the subassistant grade) is officially recognized and tolerated, there are thousands of medical men who, although trained in Government medical colleges, have received so short and imperfect a medical education that they are not admitted to the British *Register* In the third place, the I M S is primarily military, as is also the Indian Medical Department The needs of the army have, therefore, largely dominated the civil medical service, this was clearly seen in the war, when five-sixths of the officers of the I M S and the whole of the I M D were absent from their civil duties for several years In the fourth place, financial and other support is given to the indigenous Ayurvedic and Yunani systems—those medico-religious vestiges of such knowledge as was available to the world one or two thousand years ago The Viceroy and some of the provincial governors have lent their support to these systems, Indian politicians almost unanimously encourage them, and local governments, since the reforms, have in several instances voted money for their institutions and subsidized their practitioners

In view of these peculiarities in medical organization in India it is obvious that there is room for considerable adverse comment Sir Gerald Giffard drew a dark picture of the state of medical education and of medical practice generally Some of the medical schools in India, he said, are shamefully inefficient, ill equipped, and badly staffed, and it is not fair to Indian students that an education such as is supplied should be considered good enough for the bulk of the Government and local fund work throughout the provinces And as regards treatment, although there is, at headquarter towns, a more or less satisfactory hospital, the remainder of medical relief—the greatest part—is limited to hundreds of small dispensaries without beds, or with from two to ten beds, scattered over the land These deal with many thousands of out-patients, while their medical staff consists merely of a subassistant *surgeon*, who has been imperfectly trained as a student, is left with hardly any post-graduate teaching, and often becomes little better than the village practitioner and the quacks by whom he is surrounded It is deplorable that the only exponents of Western medicine to the great bulk of the people of India should be imperfectly educated, poorly paid, and isolated men, working in imperfectly equipped institutions far away from the comradeship of their professional brethren If any improvement is to be introduced in these conditions, it would appear that it can only be by the instrumentality of European medical men The future of medicine in India will largely depend on the advent of Indian medical discoveries, but there appears to be no doubt that, up to the present, Indians have shown hardly any aptitude for medical research

For more than twenty years [Sir Gerald Giffard continued] I have urged the need for research on the students and young qualified medical men in the Madras Medical College, but so far without result The great discoveries in tropical medicine have all been made by Europeans, and it would seem that further progress is dependent on European co-operation These considerations lead to the important question whether Europeans are, in fact, to form any part of the Government civil medical services in India If political India is to decide this question, the answer is No, on the other hand, if the Secretary of State and Government of India agree with the recent recommendations of the Lee Commission the difficulty of persuading young European medical men to enter the Government service in India will be very great indeed The attractions of a medical career in India used to be (1) that no capital was required, (2) that good pay was given, (3) the old Indian Medical Service officer was an Imperial officer and held the King's commission, (4) the appointments open were clearly laid down and could not be held by any but a Medical Service officer, (5) all professorships were held by Medical Service officers, (6) private practice was considerable, and (7) there was a good pension, and there was no question that it would be paid Nowadays the pension is by no means good, and it is uninsurable in London

The Lee Commission's Report [Sir Gerald Giffard continued] recommends that the I M S should be ended and that European medical officers should be obtained by provincial governments by transfers from the R A M C, as well as by recruitment of Europeans into the proposed provincial medical services But the R A M C at present cannot find sufficient recruits for its own needs, and the chances of obtaining additional recruits to serve under provincial governments seem to be remote, if not negligible The Public Services Commission is, when established, to take the place of the Secretary of State in the recruitment and control of the superior civil services in India, except those which are under the provincial ministers—in other words, those whose position is most uncertain and whose *future is most open to doubt* The Commission *Report* states "In our view, therefore, the Public Services Commission should not forcibly be intruded in the provincial field," and "that if the Public Services Commission in India should be empowered to interfere on its own initiative in the provincial domain such action will be regarded as violating the principles of the reforms" This is a very serious blemish in the report, and it appears to ring the death-knell of any European medical service in India It is impossible to conceive that any Englishman would join the Civil Provincial Medical Service under the orders of a provincial political minister without even the safeguard of being recruited by the proposed Public Services Commission It must also be noted that the Lee Report refuses to define existing and accruing right, or, in other words, leaves it to the minister to abolish as many appointments as he may choose and to refuse promotion which was to be expected when the officer joined the service If it is admitted that European medical men are still very necessary in India, the proposals of the Lee Commission will assuredly fail to attract them, and for the following reasons (1) They would deprive the future medical officer of his commission (except the R A M C India officers, who are to be compulsorily employed by the provincial civil governments, and it may be taken as certain that the latter will not employ any R I M C officer if they can avoid it), (2) they would deprive him of the protection of the Secretary of State, (3) they would deprive him of the protection of the Public Services Commission, (4) would make him serve as an equal with Indians who have an Indian degree but who would certainly be, in most cases, not as well qualified as himself, (5) they deprive him of his existing and accruing rights, or, in other words, deprive him of a certainty of promotion and of filling certain recognized appointments, (6) they put the control of his department entirely in the hands of an Indian political minister, (7) they take from him a large number of the professional appointments which are considered to be the most lucrative appointments on the civil side of the Indian Medical Service, (8) they propose to pay the medical officer a lower scale of pay and allowances than would be paid by a commercial firm to one of their employees, and (9) they do not secure him his pension In the light of these proposals, if they are to be adopted, it difficult to be optimistic as to the future of medicine in India

With regard to his own views, Sir Gerald Giffard pointed out that just as the political outlook in India is towards self-government, ending in Dominion status, to be reached

by graduated ten-yearly advances under the guidance of Great Britain and with the help of a gradually diminishing number of Europeans, so, in medicine, he desires to hear a Government pronouncement that the future of medicine in India is to be in the direction of instituting an Indian profession of medicine, similar to that of Great Britain arrived at by a slow and orderly development involving the disappearance of all medical services (except perhaps that of public health). The Lee Report recommends the abolition of the I.M.S., Sir Gerald Giffard would favour the abolition of all the medical services in India. It is the legitimate duty of Government to start or assist in starting medical education, and to build and equip institutions destined to advance medical science, but it is not its duty nor is it desirable, that Government should maintain and pay for the whole body of the medical profession.

The present state of the medical services in India (he continued) is entirely unsatisfactory. In what country in the world is there to be found a medical profession divided horizontally into layers—the members of each layer (a service) separated, as in watertight compartments from those above and below it? We have the R.A.M.C., the I.M.S., the I.M.D., the graduates of the Indian universities, the apothecaries, and the subassistant surgeons, the members of the one service being unable to pass into another. It should be possible for a qualified man to look forward to rising to the top of his profession without finding himself hopelessly handicapped from the start. It has been objected that the people could not get on if Government did not provide the services of Government medical officers. But already the great towns and many of the smaller towns could get on without the members of the Government services. General practitioners are already complaining that with the hospitals staffed by the Government service, they are badly handicapped, and that they would willingly take them over and save *much money now spent in the salaries of Government* servants, gaining for themselves the experience and the status of hospital physicians and surgeons of Great Britain, and it is probable that if this were done Europeans would be attracted to the medical colleges and hospitals of India, while it is almost certain that they will not enter the services in the present circumstances.

In conclusion Sir Gerald Giffard mentioned that a scheme suggested by him has recently been carried out by the Rajah of Panagal, the first Minister of the Madras Government. The scheme (he said) is based on the belief that the future of medicine in India cannot be a future of Government medical services. Although the medical graduates of Madras are relatively few in number many of them are unemployed. They crowd into the towns where there are already too many doctors and they have to compete there with the Government servants who absorb the greater part of the private practice. These private practitioners have usually spent all the money they can command on their education and therefore cannot make a start in the rural districts. The scheme proposes to subsidize these men and to supply them with a house for a certain number of years and a free supply of medicines and apparatus. The subsidy will gradually diminish, leaving the doctors to succeed or fail as private practitioners. The scheme is a small beginning and I hope if the recommendations of the Lee Commission are also carried out, and the professional chairs are no longer held by the services, that the handing over of the top and bottom may eventually lead to the growth throughout India of a self-reliant, self respecting, independent Indian medical profession.

In view of the development in the work among the blind owing to the operation of the Blind Persons Act 1920 the Minister of Health has reappointed the Advisory Committee on the Welfare of the Blind for a further period of office. The Committee has been constituted so as to afford representation to the local authorities concerned with the working of the Act and to voluntary agencies for the blind as well as to organized blind workers. The medical members of the Committee are Dr. J. J. Butterworth, Dr. Robert W. Lyster and Dr. H. A. Powell. The Committee will advise the Minister on matters relating to the care and supervision of the blind including any question that may be specially referred to it by the Minister.

THE HEALTH OF THE SCHOOL CHILD

SIR GEORGE NEWMAN'S REPORT

UNDER the above title Sir George Newman presents his sixteenth annual report as chief medical officer of the Board of Education.[1] The report is packed full of information on every aspect of the Board's medical work and the reports of school medical officers throughout England are freely drawn on for illustration of the subject dealt with. The volume is divided into fifteen sections or chapters, with a series of eight appendices.

The final section is entitled "Conclusions" and is summarized here as referring succinctly to the subjects treated of throughout the report. The author legitimately congratulates himself on the fact that his series of annual reports has been of use, not only at home but in the Overseas Dominions and to the governing authorities of many foreign countries. Those who are acquainted with the volumes can have no doubt that that is and must be the case. Notwithstanding his duty of advice to and criticism of local education authorities he takes the opportunity of expressing to them his full sincere and growing appreciation of the competency and devotion of their service. The present report, as he points out, is more administrative than usual because though never before has there been so much enlightened and organized effort on behalf of child welfare yet *for the success of the mutual and joint labours* of all who are engaged in the work whether officially or voluntarily good understanding and wise patient and elastic administration are essential. There must be assent of the governed, adjustment of ways and means to ends, and due regard for the susceptibilities of the child and its parents, together with willingness to undertake new duties indicated by new occasions.

During 1923 the number of elementary school children medically examined was 1,754,919 and so far as the data available show 19·4 per cent. were found suffering from serious physical defects requiring treatment. Excluding dental defects and uncleanliness the total defects treated were upwards of 650,000. The great bulk of the treatment was carried out at the 1,075 school clinics of the education authorities or at 390 hospitals under arrangement with the authorities. Some part of the work was done by private practitioners especially in rural districts. Under the authorities' schemes 473,000 minor ailments were treated, 157,000 errors of refraction of vision were dealt with, 12,000 pairs of spectacles prescribed, 47,000 operations for adenoids or enlarged tonsils performed, 32,000 other cases of disease or nose or throat treated, and 37,000 cases of ringworm. Besides all this work arising out of medical inspection there were estimated to be about 120,000 cases of physical or mental defect and for these there were 500 special schools or sanatoriums accommodating 41,000 cases. Out of 317 local education authorities 133 provided eleven million school meals a total which is substantially less than for the previous year or even for 1913-14. It is held that the *medical service* has had the effect of increasing rather than otherwise an intelligent sense of parental responsibility in regard to the importance of the health of children.

The Chief Medical Officer proceeds to urge that there are four matters requiring the special attention of local education authorities at the present time—namely, medical inspection, medical treatment, the practice of hygiene, and organization of school medical work. Inspection must be both comprehensive and exact. Nine children in ten may be briefly examined but the tenth may call for full consideration. He italicizes the dictum that a high clinical standard of work is necessary. Also the education authority should take a wide view of its function. It could investigate absenteeism due to long standing mental defect, should ascertain the character and degree of defects, could inquire as to obscure infective diseases like encephalitis and poliomyelitis, and should make research as to physical standards and physiological variation.

Concerning medical treatment he told that though no less than half a million children were treated in 1923 in areas outside the large towns many authorities have not made satisfactory provision. Eighty-three have no available *organization* for diseases of the nose and throat, 67 have

no organized dental treatment, 164 have done nothing for ringworm, and 14 still neglect the treatment of defective vision. Also, especially in rural districts, there is a serious difference between the number requiring treatment and the number receiving it. More might be done in following up, in making treatment available, and in prescribing the duties of the medical staff. The essential conditions of child health are, first, good eyesight and hearing, second, physical strength and muscular development, and third, sound digestion and assimilation of food. In other words, eyes, ears, physique, and teeth are the fundamentals for medical attention, as illustrated by the main grounds for rejection in 1920-21 of 360 per 1,000 of recruits offered for the army.

Next, as to personal hygiene in the case of school children, this is a matter mainly of education rather than of sanitation, and is perhaps the most important subject of the whole curriculum. Yet Sir George Newman declares—

"The plain fact remains that training colleges afford insufficient attention to this subject, and many local education authorities devote less attention to it in the school than is given to any other prescribed subject of the official curriculum. The teaching of hygiene and the laws of health by systematic instruction and by daily practice, should be undertaken in every school throughout England and Wales."

Finally, as to the organization of school medical work, it is advised that local education authorities should have regard (1) to the soundness and integrity of their scheme, and (2) to its proper association with the local public health service. Their own services should be uniform and comprehensive, its essentials being thorough medical inspection and the ensuring that medical care and treatment is available. An adequate medical and nursing staff and an efficient school clinic, though the best method, may be of little use without following up, and 'owing to unwillingness and inattention rather than lack of knowledge or means, there are still many children deprived by the authorities of the minimum advantages of a medical service which Parliament has definitely declared they must have." Also children who are blind or deaf, or physically or mentally defective within the meaning of the Education Act, 1921, can only have proper provision made for them by means of a prolonged and serious effort on the part of the local education authorities. Only about 40,000 of 150,000 are at present in special schools. To ascertain all such children in their area is the duty of every education authority separately, to provide for them will nearly always require co-operation. Sir George Newman remarks that progress is being made in the usual English way, by spasmodic efforts to meet needs as they arise, and the piecemeal devising of a national scheme. The report concludes as follows:

"The present time seems likely to provide a landmark in the history of the school medical service. Everything is ready for further advance. We have in most matters ample knowledge as to what ought to be done, we have learned by experience how best to do it effectively and economically, we have an organization at hand simple well tried, and capable of expansion as required. It is not that there are great extensions or exceptional achievements to record for 1923, but owing to somewhat less financial stringency, and owing to consolidation and a fuller appreciation of the value of the service in regard both to the treatment and the prevention of disease among children there is high promise of wide and fruitful development."

Having devoted so much space to the conclusions of the Chief Medical Officer, not very much can be said of the many important matters dealt with in the sections which compose the report. A few points, however, noted in perusal of the volume, may be mentioned.

(1) Many of the school buildings are defective, especially in some rural areas, some having fallen below a reasonable health standard owing to money stringency in recent years. The six most frequent sanitary defects are unpaved or unsuitable playgrounds, lack of water facilities, inadequate cloakrooms, uncleanly classrooms, insufficient heating in winter, and unsuitable desks.

(2) The alleged decadence of the rural child in Devonshire is the subject of a startling report by Dr. Corkery, school medical inspector there, quoted by Sir George Newman. It is partly as follows:

"The steady and manifest decline in the general physique, appearance, and stature of the rural child prompted me to select this theme for my special report for the year. The country bred child was in former years far superior in health and vigour to its less fortunate sister and brother who were reared in a town, and the difference in appearance and health was obvious to the most casual observer, but the rural child has now lost its heritage and the town bred child is now wearing the lost mantle. One formerly pictured the country child with a chubby face, pink cheeks, bright alert eyes, and sturdy figure, the 'Devon Dumpling,' in other words. Now you find many of the children in country schools (excepting the children of farmers) are pale faced, anaemic looking, with eyes lacking lustre, undersized, underfed, and sad faced, and without the *joie de vivre* expressed in their general pose and countenance. Why this change? That there has been a steady and progressive decline in the general physique of the majority of country children is abundantly manifest, nor is the decline associated with any special area, but exists practically all over the rural areas, even in moorland children, though I believe in the latter classes different causes operate. The chief factors causing this decline of health are, in my opinion (1) Migration of the 'fit' from the country to the town and consequent breeding from the unfit (2) Bad housing (3) Lack of sufficient and suitable food (4) Intermarriage (5) Large families."

It is most important to know whether this represents the general experience of school medical inspectors in the rural districts.

(3) Action with regard to school closure for infectious disease has been revised. Such closure has hitherto been carried out in the financial rather than the medical interest, exclusion of individual children having led to loss of grant, which loss was prevented by complete closure, resulting, of course, in loss of education, the primary purpose of the school. That paradox is now to be remedied.

(4) Co-ordination of the work of the school medical officer with that of the certifying factory surgeon in respect of determining the fitness of young persons for employment in factories has been the subject of inquiry by a parliamentary committee. The committee's report was published in May, and in that month a clause was introduced into the Factory Bill then before Parliament. That bill (which, like many other departmental bills, lapsed at the dissolution) contained provisions dealing with the matter.

(5) *School Meals.*—In regard to this matter the report states:

"It is provided that there shall be charged to the parent of every child in respect of every meal furnished, such an amount as may be determined by the authority, unless they are satisfied that the parent is unable by reason of circumstances other than his own default to pay the amount."

In fact the figures show that parents from the beginning have contributed the merest fraction of the cost. In 1913-14 the total expenditure was £147,519, while the amount received from parents was only £2,997. The year 1918-19 appears to have been the best in this respect, the total expenditure having been £137,071, and the parents' contribution £21,902. The most recent year in the table is 1922-23, when the total expenditure was £281,251 and the parents' contribution £17,197. The year 1921-22 was altogether exceptional in outlay, the amount being £983,182, to which the parents contributed £15,822. The average cost of meals in pence ranged from 2·43 in 1913-14 to 6·99 in 1919-20. In 1922-23 the cost was 3·93 pence. A report quoted from Shropshire states that "the scheme should be self-supporting by means of small contributions from the parents," and in Kent, where there is a canteen system, "most of the canteens are now self-supporting," and "the number of meals supplied during the year ended March 31st, 1923, was 109,926. The number of meals supplied in return for payment by parents or funds raised locally was 161,751. At milk nutrition clinics under the London County Council 788,668 milk meals were given to necessitous children either free or for part payment, while 1,841,311 milk meals were paid for by parents in full."

(6) In the section dealing with research it is stated that special inquiries are to be made into the following subjects:

"(1) The incidence of disease among children under the age of 5 years. (2) The prevention of adenoids and enlarged tonsils. (3) The prevention of defective vision and squint. (4) The establishment of norms in regard particularly to height, weight, and nutrition generally. (5) The character, incidence, and prevention of rheumatism in children. (6) The study of encephalitis lethargica with special reference to after care and education. (7) Problems presented by the mentally defective child. (8) The incidence and significance of goitre."

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER

(Continued from page 968)

THE eleventh sitting of the Royal Commission on Lunacy and Mental Disorder was held on November 18th, Mr H P MACMILLAN, K.C., presiding.

Evidence of Medical Superintendents of Mental Hospitals

Dr J. FRANCIS DIXON, medical superintendent of the City Mental Hospital, Humberstone, Leicester, gave evidence. Asked for any suggestions for the simplification or improvement of the code under which such institutions as his were worked, witness said that if some of the legal enactments were strictly interpreted innumerable difficulties could be raised, but if one could just go behind the letter of the law many of them would be overcome. He gave as an illustration the continuation order—a form for the purpose of continuing the original reception order. Under this order the medical superintendent had to state that in his opinion a patient was still insane and a proper person to be detained, and he admitted that he felt some embarrassment in giving a certificate of continued insanity in cases of convalescence or recurrent cases which might have a lucid interval lasting a year. He had, however, no doubt as to the desirability of the continued detention of the patient for a time, and during the convalescence of patients he frequently took advantage of the power he had to allow them out on trial.

The CHAIRMAN said that suggestions had been made that in the incipient stage it might be desirable to avoid the stigma of certification by some expedient, and he asked whether this might be met by the issue of a continuing certificate in a modified form. The witness thought that the form already in existence might be modified. He did not think it was necessary to say that the patient was still of unsound mind.

Asked whether he had encountered any cases in which on examination of the patient admitted he was satisfied that they were not proper cases for detention, Dr DIXON said that he had encountered cases in which he was unable to confirm the statements made in the certificate on which the patient was admitted. That, however, was a somewhat delicate matter, because although a patient might have had all the qualities assigned to him before he came in, these might not be present on his examination in the institution. If the medical superintendent had to say in his first report that the patient was in his opinion insane, he would meet with a considerable amount of difficulty.

The witness went on to deprecate the machinery by which a patient was compelled to go before a magistrate prior to certification, in that it created in the patient's mind a feeling that he had committed some wrong and was in the hands of the law. With regard to the suggestion that patient were detained when fit to be discharged, especially because they were found useful to the institutions, witness said that there was every possible reason why patients should be discharged if only because the more cures a medical superintendent effected the higher became his reputation. As to employment in the institution, there were always a number waiting to replace those who could be discharged. In his institution patients were classified first of all not according to their disease, but according to the amount of liberty that could be given them. He attached great importance to proper classification from the outset, and to adequacy of accommodation for this purpose. In suitable cases, of course, definitely curative treatment was undertaken. There was no some improvement with regard to the conditions under which the nursing staffs of mental hospitals worked, but it seemed to him that the seniors did not receive sufficient remuneration, whilst the juniors in training were overpaid. In his opinion mental nursing called for a very much higher kind of work and greater personal qualities than did general nursing.

In reply to the Chairman, Dr DIXON said he thought it very desirable that persons with incipient insanity should be able to obtain treatment without necessarily being certified as insane. At the same time he thought that the stigma attaching to certification in the public mind was due to a misconception, probably due to past traditions with regard to the malady, and would diminish, though perhaps not entirely disappear, with general enlightenment. The Chairman asked whether it would not assist in removing that conception if people were treated in the first instance in homes or institutions which partook of a hospital rather than of an asylum character, where they might be detained for a period before being finally stamped—should this be found necessary—as insane persons. The witness said that this might even be carried further, and nobody at all be certified if the mere certification was the bugbear, it would be possible to keep on renewing the temporary order. Certification was simply a protection to those who were dealing with a patient who required or might require some restraint; it might answer the same purpose if the doctors and not the patients were the certified persons. In reply to questions from other members of the Commission the witness said that his own institution accommodated 1,600 female patients and about 330 male. The number of patients at the end of 1923 was 842. During that year there were 168 admissions, of which number 39 were readmissions. The rate of recovery was 37·12 per cent. of admissions. With regard to procedure on admission, if it was decided that the rate-aided patient should have the benefit of two medical certificates as had the private patient, one of these certificates, if possible, should be made out by the patient's medical man, and the other by a medical man specially qualified or specially appointed for the purpose. Earl PEEL suggested that it would be an improvement if a person, instead of being described on the reception order as a certified lunatic, were described as a mental case under compulsory treatment. Witness agreed that it would be well to start afresh and use some other word than lunatic.

Dr O. G. CONNELL, medical superintendent of the North Riding County Mental Hospital, Thorpe, was the next witness. He said he had paid some attention to the safeguards against undue detention of persons in mental hospitals. The principle of the reception order was sound, but he thought the same procedure should be adopted in the case of the pauper as in that of the private patient, particularly in the respect that two medical certificates should be necessary. He agreed that many cases were so clearly certifiable that the second certificate would be redundant, but occasionally a patient was presented for admission who was not a lunatic although certified as such and detained for a week, with two certificates this was less likely to happen. The Chairman said that in borderline cases or cases of any difficulty it might be very proper to call in a second opinion, but to make it an invariable procedure would be very expensive. Answering questions with regard to his own institution, the witness said that in 1923 the recovery rate was 35 per cent. of admissions, and so far during 1924 it had been 45 per cent. This of course was below the rate in some other institutions where the figure might reach 70 per cent., but it had to be remembered that these figures were not entirely governed by the rate of recoveries, they were governed by the number of patients who were suitable for discharge and for whom suitable outside care was available. The number of admissions during the present year was 197, of which only 7 were readmissions. He thought that cases likely to benefit by treatment should not be certified, they should come in as voluntary cases. At present he had no power to admit a patient who came voluntarily, and in one case in which such a patient came to his institution and insisted on remaining, the only thing he could do—he admitted it was an absurd thing, under the circumstances, but he had no alternative—was to refer her to the police. Some patients who had been in the institution were quite ready on any recurrence of the malad to return.

The Chairman pointed out that the difficulty of the Commission in recommending action with regard to voluntary cases was that although as the witness had stated mental illness was on the same basis as physical illness, the former struck at the citadel of reason, so that some means of detention or restraint had to be available, moreover there could be no dependence on mental illness upon the co-operation of the patient in measures taken for his own recovery. Dr Connell agreed that if voluntary patients were admitted to a mental hospital some measure of control and power of detention must be permitted. He thought it would be sufficient if it was laid down that such a person could not leave the institution without a certain period of notice. Possibly seventy-two hours—the period mentioned in the Mental Treatment Bill which was before Parliament last session—would be sufficient, so that in the event of a breakdown the patient could be prevented from discharging himself for a time sufficient to enable the medical superintendent to get in touch with his relatives, guardians or the relieving officer and take measures if necessary for certification. Some provisional or emergency order would be requisite if voluntary patients were to be taken. With regard to after care, the outstanding difficulty was the shyness of people to recommend for employment anyone who had been in an asylum.

The witness was questioned also with regard to complaints of ill treatment. He said that in his own institution during the three years of his superintendency only two cases had occurred, both of them really of a trivial nature, so far as any injury to the patient was concerned, but both of them followed by the dismissal of the attendant because it was essential to maintain the greatest discipline in these matters. In one case a refractory patient had received a slap and in the other a nurse, in more or less involuntary self-protection against an action of the patient, hit the patient on the head with a broom causing a slight wound. In reply to Sir David Drummond, the witness said that he thought more provision should be made for the study of insanity in the curriculum of the medical student. Doctors entering their profession had very little knowledge of insanity, although they acquired knowledge subsequently by experience.

Paris.

[From our own Correspondent]

November finds the medical profession of Paris in its normal state of activity. With the advent of October *la vie médicale* showed the first stirrings of reawakening after the lethargy of summer. Since the war the laity has won the right to a period of rest each day and each week, but the doctor is obliged to wait until his annual holiday. Strange consequences are therefore observable, particularly in the domain of surgery, and visitors to France find it difficult to understand why closed doors and silent telephones confront pilgrims seeking those of our celebrities whose fame has travelled beyond our frontiers. Emergency cases have to be content during the holiday period with theatres deserted by the stars of surgery, *hospital work* is carried on by the junior staff, and teaching comes almost to an end. Meanwhile our invalids journey instinctively to the particular watering-places chosen by *our profession* for its summer retreat.

Thermal Treatment

The ever-growing fame of thermal treatment is a curious *phenomenon* of this post-war world. Highly specialized French spas have verily now become provincial schools of medicine, and intensive propaganda has resulted in each set of "baths" being labelled like an advertisement. We find accordingly baths for the liver, for the heart, and for the kidneys, or, again, we have baths for the "algias," for hypertension, and for constipation. Such a classification, admittedly convenient, is, alas, not tuned to the subtle requirements of clinical treatment. While we *grow under this crude notoriety of press and poster*, we must needs take things as we find them.

The Age of Official Medicine

It is sometimes necessary, nevertheless, to school ourselves to view things as they will be, and to picture the future reconstruction of our professional life after the revolution heralded to-day. It is highly probable that the Parliament elected last May will enact insurance legislation on the lines approved by the previous Parliament. This legislation has a basis of electoral approval, and so the majority parties will, doubtless, unite again to present this handsome gift to their supporters, the bill being paid by the medical profession. So begins an age of State medicine, which will bring about the transformation of the doctor into a bureaucratic official. It may come clad in the outward semblance of a forward movement, but for us it disregards the essential principles of our charter of medicine—namely, professional secrecy, and free choice of doctor. Every such foreshadowed law, and every official regulation which threaten these principles, *ought then to* be met by the resolute opposition of the *profession* banded together. We have, unfortunately, *no organization comparable with the British Medical Association, and so we* can only trust that such a body may spring into being in this hour of peril. It is inherent in the French character *to set about organizing* only under the pressure of immediate circumstance.

From the point of view of those who advocate this law the *doctor* is simply a "producer": he produces treatment just as other people produce chocolates or shoes. The intangible elements in our work are not taken into consideration at all. Could the realities of medical practice be more absolutely misconstrued? They offer us a general contract, a central fund, a *book of coupons*, a system of control complete with controllers, and a remuneration so low as to compel the *doctor to compress the maximum number of visits into the minimum time*—in short, the "commercialization" of medicine. How, then, will the French doctor, jealous of his rights and *essentially a critic*, behave? Yet without his help the law cannot come into effect. Will some compromise be found? This we shall learn in the near future. Our profession stands firm on the sacred principle of professional secrecy. It is, moreover, the *right* which guards our honour—a right to *repel on the one hand* this threatening law, and, on the other, the Treasury exaction which *would compel* us to keep an account book inscribed with the names of our patients and the fees paid. We refuse to write down in black and white such an entry as this: "Madame A, three intravenous injections 300 francs," in order that the Treasury inspector may come to Madame A to inquire if perchance she has been charged excessively in the treatment of an illness admittedly of a private nature. As an illustration of the length to which equality mania can be pushed in a democracy, it has actually been suggested that professional titles should be taxed. The chief of the Paris Faculty has uttered a public protest against this absurdity.

Auguste Broca

With the passing of Auguste Broca at the moment when we were celebrating the centenary of his father, *le grand Broca*, there disappears one of the most typical Parisian surgeons of our time. His professional dignity and stern scientific uprightness will long remain as a great example to be copied. He had a most warm-hearted nature, coupled with impulsive liberality. This impulsiveness rendered him famous, especially when he was called upon to defend his opinions or his principles, for which he fought battles with tongue and with pen. During the last years of his life, to the amazement of the world, he was with difficulty stopped from rushing, sword in hand, into a fight with one of his colleagues in a personal quarrel. With Broca have passed away Talamon, Richelot, Hallopeau, and Rochard: this has been a very cruel year for the surgeons of Paris.

Scotland.

Measles and Whooping-cough in Edinburgh

A circular has been issued by Dr. Robertson, Medical Officer of Health for the City of Edinburgh, intimating that, in view of the prevalence of measles and whooping-cough in the city, the Town Council has decided to pay a fee for the notification of the first case of measles and whooping-cough occurring in any house. The object of this notification is to apprise the Public Health Department of the existence of cases of these diseases, so that home visitation by a qualified nurse attached to the Public Health Department may be carried out. It is not intended, however, that the visits paid by *the nurses should be pressed in cases* where they are not desired, and the medical practitioner who makes *the notification may indicate* on the form if he does not *consider it desirable or necessary* to have such visits paid. It is hoped by these measures to reduce the incidence and death rate from measles and whooping cough, *especially among children* under 5 years of age. Attention is drawn in a notice to the public to the fact that these two diseases of young children cause a greater number of *deaths than* diphtheria and scarlet fever. For instance, during the three years 1921, 1922, and 1923 the total number of deaths from diphtheria in Edinburgh was 140, and those from scarlet fever 103, whereas during the same period the total number of deaths from measles was 258, and from whooping-cough 273. Extra accommodation has now been set aside at the City Hospital for infectious diseases in order to deal with children whose retention at their own homes is decided by *the medical practitioner* in attendance to be unsuitable. The Medical Officer of Health appeals to parents to assist him in his effort to have children removed *to hospital* before the onset of bronchitis or pneumonia, for the treatment of which many homes are quite unsuitable. He also points out that it means a great deal to the children's future health if a thoroughly good recovery is made from measles or whooping-cough.

Aberdeen University Lord Rector

Viscount Cecil of Chelwood (Unionist) was *elected* Rector of Aberdeen *University* on November 15th, having a majority of votes in each of the four "nations" by which the election at this university is made. The four "nations,"

into which the votes are grouped, are Mr. Buchan, Moray, and Angus. The result of the voting was: Viscount Cecil (Unionist), 449 votes, Lord Meston (Liberal), 240 votes, and the Right Hon. C. P. Trevelyan (Socialist), 101 votes.

Parents and Public Health

An address was given last week by Councillor W. J. Harvey, convener of the Public Health Committee of Edinburgh Town Council, to the Friendly Societies' Council of Edinburgh and Leith on the subject of public health. He said that recent public health legislation was sometimes subjected to the criticism that it had undermined the independence of the individual and lessened the personal responsibility in health matters. The collection of the population in large centres had, however, made it impossible for man to fend for himself and had made State provision imperative in many directions. In man's social life there were four forces which threatened him communally and individually. These were insanitation, ill health, poverty, and indifference. With regard to the last, the attempt which was made by the parent to acquire fuller knowledge of child dietetics, hygiene, and similar subjects, and the encouragement to attend clinics, did not tend to lessen personal responsibility. On the contrary, these factors should be a call to a fuller sense of responsibility by realizing the needs of the moment in order to assure a healthy future for children. The most difficult obstacle which public authorities had to overcome was indifference and irresponsibility, and public health authorities, while they did not intend to undermine responsibility, rightly attacked the indifferent and irresponsible.

Letters of Mary Queen of Scots

An appeal has been issued, under the patronage of H.R.H. the Duchess of York, for subscriptions in aid of a fund to purchase, on behalf of the Scottish nation, a number of letters and documents relating to Mary Queen of Scots. An option has been secured to purchase these papers for a sum of £2,250 in order that they may be lodged in the Advocates' Library at Edinburgh, shortly to become the National Library of Scotland. That library has already become the repository of some valuable historical letters relating to the same queen, which were purchased in June, 1924. The papers consist of thirty items, including nine letters signed by the Queen, one signed by Henry Lord Darnley, two letters from Queen Mary of Guise, two from James, Earl of Arran, one from the Earl of Lennox, Darnley's father, two from the Earl of Morton, and two from King James VI. The letters came originally from the family archives of John Muir, Laird of Rowallan, a prominent supporter of Queen Mary, and they are mostly unpublished. Persons willing to subscribe to this fund should intimate their subscriptions before November 30th to Dr. C. Stewart Black (Honorary Secretary, St. Andrew Society, Glasgow), 93, High Street, Paisley.

Central Midwives Board for Scotland

The examination of the Board held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen has just concluded with the following results. Out of 126 candidates who appeared for the examination, 102 passed. Of the successful candidates, 24 were trained at the Royal Maternity Hospital, Edinburgh, 23 at the Royal Maternity Hospital, Glasgow, 4 at the Maternity Hospital, Aberdeen, 14 at the Maternity Hospital, Dundee, 10 at the Queen Victoria Jubilee Institute, Edinburgh, 8 at the Cottage Nurses' Training Home, Govan, Glasgow, and the remainder at various recognized institutions.

Ireland.

Milk Supply of Dublin

Professor Joseph Bigger, M.D., in a lecture under the auspices of the Royal Dublin Society, delivered in the Royal College of Surgeons, Dublin, said milk was a valuable food, and contained all the necessary food materials. One pint of milk costing 3½d., supplied the same energy as 12½ oz. of beef (1s. 3d.), five eggs (1s. 3d.), four bananas (8d.), 1½ oz. of butter (3d.), or 6 oz. of bread (1d.), so that it was a fairly cheap food. Milk was often adulterated by the subtraction of fat and the addition of water, but its chief dangers were from bacteria. Dublin milks contained on an average 600,000 bacteria per cubic centimetre in winter and 4,000,000 in summer. Tubercle bacteria of the bovine type were found in 8 per cent. of milks bought in Dublin. This organism can and a considerable amount of tuberculosis in children. Other diseases spread by milk were typhoid fever, scarlet fever, and diphtheria. Dirt bacteria came from the cow's excreta, and were the cause of infantile diarrhœa. The milking methods at present in use were unsatisfactory, and were the cause of the excessive numbers of bacteria in milk. It was shown that an ordinary labourer could be taught how to produce clean milk in a few days with practically no expense. The conditions under which a pure milk supply had been procured in the United States and Great Britain were explained by the lecturer, and he made suggestions for the procuring of clean milk in Dublin. For the best quality the cows should be tested by tuberculin, the methods of milking should be satisfactory, the milk should be supplied in bottles, and should pass a bacteriological examination. Such milk would cost more, but economies could be effected in delivery, only one delivery a day being necessary, as clean milk would not sour within thirty-six hours. Pasteurized milk was considered less satisfactory, but was much better than the milk now sold in Dublin. Anyone found selling filthy milk should be imprisoned and prevented from selling milk thereafter. The chief danger to health arose from the dirty handling of milk. About 2 per cent. of cows suffered from tuberculosis of the udder, and it was a possible danger to the community. Another cause of contamination was that the flanks of cows were allowed to be covered with dry manure, indeed the chief source of bacteria in milk was cowdung. Filtration did not remove the dirt. By clean methods milk should remain sweet for 183 hours, and these methods could easily be improved. Milking pails and buckets should be sterilized by steaming. Milk should be kept in a place where there were no odours of food or paraffin oil, and at the lowest possible temperature. In Dublin the same price was paid for bad as for good milk. Forty-eight per cent. of the milk sold in Dublin ought to be condemned as unfit for human food. It was essential for the health of the community that the public should demand clean milk. Professor Bigger regarded the present price of milk as excessive. Milk dealers were able to supply hospitals at contract prices enormously below what they charged the public. Good milk did not require heating; bad milk should not be heated. The speaker pleaded on behalf of the babies of Dublin who acquired tuberculosis and became cripples through the dirty milk which they drank. Persons who sold dirty milk were really poisoning the life of the city. If public interest were aroused in the subject it would be possible to secure a satisfactory and clean milk supply.

Presentation to Dr. William Gibson, Belfast

On the evening of November 12th Dr. William Gibson, sanitary surveyor and inspector of emigrant ships, Belfast, was presented with his portrait in oils, to be hung in the hall of the Willowfield Unionist Club, and with a replica and a portrait of Mrs. Gibson for their home. Dr. Gibson has been long known for his labours on behalf of the Unionist cause in the North of Ireland, but this work has always been combined with genuine and broad philanthropic leaning. He was mainly responsible for the erection and equipment of the Willowfield club and hall, situated in a densely populated district where all could meet and enjoy social intercourse, and where friendly relations between all classes of the community were promoted; provision was made for the enjoyment of members and a high sense of citizenship fostered. Dr. Gibson has been busy all through his life with innumerable undertakings; during the war he was secretary of the medical board of the Ulster Volunteer Force Hospital, where all who wore His Majesty's uniform were admitted; he was an active member of the Belfast Ambulance Committee which supplied all the ambulances of the Ulster Division, and he was still engaged in the Hilden Hospital and in the Joint

Committee of the Red Cross and St John His civic labours also were many, varied, and always energetic and for the good of the people The Prime Minister of Northern Ireland (Sir James Craig), the Lord Mayor of Belfast (the Right Hon W G Turner), and many others were present, and spoke of Dr Gibson's indefatigable public labours, the Right Hon H M Pollock, D L, M P, Minister of Finance for Northern Ireland, proposed the toast of "Our Guest," and the Prime Minister unveiled the portraits Dr Gibson, in his reply, described the origin of the Willowfield Hall in which they now sit, it was free of debt, and they were already engaged in raising funds for the purchase and equipment of playing fields for the outdoor enjoyment of the members He desired to thank all those who had joined in the promotion of the enterprise, their memorial tablet to the sixty-four members who lay in Flanders fields was always a stimulus to such work

Correspondence.

SCIENCE OR ART?

SIR,—Not even the eloquence of a leading article will persuade the majority of us that medicine is a science It is something greater it is an art Medicine is the greatest of all the arts, and all the sciences are but its helpers

This conception of medicine is of great antiquity The Pericles in Greek, with his clear insight and his wonderful power of penetrating to the heart of a matter, accepted it "Medicine is of all the arts the most noble," wrote Hippocrates, whom Plato grouped with Pheidias and Polycletus

Science is obviously of vast importance, to medicine it is indispensable, but it is auxiliary only Science is the scaffolding without which medicine cannot be built up but it is not the building It is the machinery by which the worker works, but it is not the worker, nor his work

The conception of medicine as a science is more than a mistake that is why one takes the trouble to discuss it It is really mischievous For if medicine be a science, then, logically, our patients are primarily material for experiment That, we know, is the German idea But if medicine be an art, then the good of the patient is the end of all our effort No saveable life lost, no preventable suffering unprevented, is other than a deplorable failure, be the scientific aspect what it may" That is the English idea

I repeat, medicine is the greatest of all the arts, and all the sciences are but its helpers Its material is the most precious in the world its triumphs have been the consolations of humanity It gains nothing by being misnamed a science —I am, etc,

W GORDON

Exeter Nov 16th

THE GENERAL PRACTITIONER AND THE MATERNITY SERVICE

SIR,—Your important leading article in this week's issue of the BRITISH MEDICAL JOURNAL (p 911), the combined discussion at the Royal Society of Medicine on November 6th (p 900), and also Dr Gibbon Fitzgibbon's illuminating letter (p 927), encourage me to add one more to the quota of facts steadily accumulating as to the part played, or perhaps that should be played, by general practitioners, the "institutions," and the local health authorities in the prevention of maternal mortality

The point I would accentuate is, I think, important, especially as it seems to have been overlooked by many contributors on this subject, notably Dr Bennett (BRITISH MEDICAL JOURNAL, October 18th, p 741), and not mentioned by Dr Fitzgibbon It is that "hospital treatment" is not necessarily synonymous with the best obstetric skill It is doubtless so in London and the really large centres, but in many other parts of the country the "hospital," the "Poor Law institution," the "fever hospital," or the "cottage hospital" are not necessarily—in fact are not—staffed by obstetric surgeons, or even perhaps by any interested in the matter

I draw attention to this so that the administrative scheme shall cover this important detail, if and when it is evolved, and all of us with a desire to reduce this terrible scourge hope that reform will not be long delayed —I am, etc,

Norwich, Nov 15th ARTHUR CROOK

SIR,—Your appeal to the general practitioner in the JOURNAL of November 15th to ventilate his views on this subject induces me to give my impressions of the practice of obstetrics As I have an experience of over thirty-four years behind me, my suggestions for improving the position may possibly be helpful

In my early days the qualified midwife had not come on the scene and we were dependent on the 'handy woman" to help us With the advent of the trained and certificated midwife matters were much improved, and the harassed and often overworked practitioner was not called on to spend so many useless hours at a case, or tempted, in the alternative, to risk "getting it over" with the aid of forceps

The pendulum, however, has now swung too far, as the majority of cases are attended from first to last by midwives alone, the doctor's services not being requisitioned till something has gone wrong Some patients, when expecting confinement, only *provisionally* engage a medical attendant, saying, "Will you come, doctor, if we want you" Naturally they do not send if they can possibly do without, on account of the expense And as most doctors dislike midwifery they do not worry But this practice opens the way to serious mishaps, and is altogether wrong I will illustrate what I mean by two fairly recent experiences

In the first I was provisionally engaged to attend a lady in her second confinement I had attended when her first child was born in a perfectly normal confinement When summoned on the second occasion I found that the midwife had been in attendance four days, the membranes ruptured two days—"a hand down" and, of course, the child dead Version was very difficult and the patient very seriously exhausted Result, sepsis—which by the way, I do not think I notified, as it was of the type often seen in such cases—sudden rigors, a rapid rise of temperature to 104° F or over, falling to normal in twenty four hours or less Incidentally I was blamed for the patient's condition, although the midwife was in attendance at several other febrile cases Happily a good recovery was made

The second experience illustrates where the present practice of midwifery is at fault Here, again, the case was one of cross presentation, which, however, the young practitioner in attendance could not rectify single-handed His partner, not taking on midwifery engagements, asked me to go and help, which I did With some little difficulty delivery was safely effected, and I believe the patient, after some febrile disturbance, recovered The point here is that the first practitioner probably lacked experience and the skill which only comes with experience It called in earlier, perhaps things would have been different I cannot remember if there was a qualified midwife in attendance I rather think not, and I was not called on to see the case again

Now, Sir, I do not see how the notification of puerperal sepsis is to help us in such cases as these By itself, it certainly will not prevent sepsis, and to my mind it will always be an unsatisfactory procedure, at any rate as it present carried out What is the use of training and licensing midwives to act alone in the management of labour, and leaving the young graduate helpless in the frequent emergencies for want of experience? The factor of time is all-important in many cases, and removal to a suitable hospital is not always either desirable or possible

The remedy, to my mind, is a simple one, though probably it would require legislation It is, *that in every case of confinement a medical practitioner be called to attend at least once, preferably at the beginning of labour* This may sound a drastic step, and put forward to benefit the medical profession alone, but when examined closely I believe it would have the happiest results—to the patient, the nurse, and the doctor It certainly would re-educate the mind of the public generally, bringing them to see their own responsibility in this grave matter of maternal mortality in childbirth —I am, etc,

ALEX P AGNEW, M B, C M

Wymondham, Norfolk, Nov 16th

SIR,—In your article on the general practitioner and the maternity service you comment on the fact that only one general practitioner took part in the discussion. The fact is deplorable, but it is readily explicable.

The truth is, that the average general practitioner is a little weary of the innuendo that he alone is responsible for the high rate of maternal and infantile mortality. He is not even allowed to *divide the opprobrium* with the midwife. For example an article in the current issue of a journal of popular medicine states: "The greatest factor in stillbirths and maternal mortality is undoubtedly delivery by forceps. It is, further, the greatest cause of subsequent sepsis." Such exaggerations hamper the work of the general practitioner and seriously impair his relations with his patients. It is not surprising that he finds it more compatible with his dignity, and his self respect, to hold his tongue.

Hitherto, his practice has been the product of his teaching, and it is *unreasonable to blame him for procedure* which was universally taught until the last few years. Anyone who will take the trouble to look through the textbooks of only a few years ago will, I am sure, agree with me on the matter. Many eminent teachers of midwifery have frankly admitted that their views have profoundly changed during the last few years, and they will no doubt collaborate with general practitioners to evolve a practicable system of midwifery which cannot fail to benefit the community. No advance will be made by the persistent advocacy of methods which the conditions *of general practice render impossible*.—I am, etc.,

London, E12, Nov. 1st. A. CAMPBELL STARK.

SIR,—In a pertinent leading article this week you inquire why the general practitioner seems to take so little *interest in the maternity service dispute which*, as you very justly remark, is "now raging." May I venture to suggest in reply that this dispute has not yet shown any promise of a practical outcome—the only note likely to arouse harmonious response amongst general practitioner. Not only is there no sign of practical outcome, but the dispute has passed into the realms of broad farce—I do not think that such a term is too harsh for the discussion which you report on notification. There is also more than suspicion amongst general practitioners that they have been most unjustly condemned (for example in Dr. Janet Campbell's report) for something which is not their fault. Nor are those practitioners who have given special consideration to the subject unaware of the very slender basis of scientifically established fact which underlies the fulminations of the experts. The expert does not always seem to realize how slender it is, and I venture to elaborate the point in the hope that more attention may be given to it.

The thesis of Dr. Janet Campbell, Dr. F. G. Stevens, and others is that puerperal fever is due in the vast majority of cases to some fault of the doctor or midwife. This thesis ought to be submitted to scientific examination. It is in danger of becoming accepted by the public, to the vast *detriment of everyone outside Harley Street*.

The doctor or midwife is in attendance at the vast majority of labours so that the *post hoc ergo propter hoc* argument is inviting. No more valid argument has yet been adduced by the experts. Yet if it is to be accepted it should at least be shown that puerperal fever is more frequent in those parts of the country in which sepsis is most prevalent or doctors most careless. In fact all statistics suggest the opposite. Or it should be shown that the usual causative germ is one which is most commonly encountered on the doctor's hand (which is not the case) or that the disease is less common when the case is handled by an expert (which has yet to be proved) or that it *does not occur when labour has not been assisted* (which is not so). The '*post hoc*" argument is too slender a stick to depend on, and the experts are hereby invited to produce something more convincing, and in so doing perhaps they will also explain the remarkable prevalence of an apparently identical fever amongst cattle in which there is no midwife or doctor or self-examination or coitus during pregnancy.

It is true that certain experts suggest no more than that the doctor and midwife (however clean their hands) convey germs from the vagina into the uterus and so set up puerperal fever. No evidence is offered other than the possibility of such happening. The general practitioner would like to know from these experts exactly what steps they take to secure that the vagina shall remain aseptic *during the whole of labour* and whether they succeed in thus limiting puerperal sepsis. We shall then be able to judge whether such steps are within the range of practical politics in general practice and also whether the fees allowed by the State would permit their employment. Another way in which the anti-practitioner case is stated is that puerperal fever is due to his omission to do something which he ought to do—for example, to wear gloves or to sterilize his instruments properly. The proof offered is ludicrous—namely, that in such and such a case gloves were not worn and fever occurred, in fact the '*post hoc*" argument again. It has yet to be shown that there is any relation between the wearing of gloves and puerperal fever (even ordinary surgical) sepsis.

Other illustrations might be given but enough has been said to suggest, and to suggest very strongly, that the maternity service dispute shows more signs of ill informed prejudice than of scientific investigation. The truth is that practically nothing at all is known about puerperal fever. The available reports on its bacteriology are conflicting and few in number. Its distribution in relation to types of dwelling, etc., has scarcely yet been studied. Of factors *predisposing to it, nothing* is certainly known except that there are such factors. Its curative treatment is unsatisfactory and *often futile, nor are the details of it agreed*. Its prophylactic treatment (very successful in the hands of veterinarians) is apparently unknown to gynaecologists. And in this fog of ignorance wander those who have facilities of which the general practitioner can only dream, and they have altogether neglected those facilities in order to rail at the criminal carelessness (assumed) of midwife and doctor.

Surely, Sir, it is no wonder that the general practitioner takes little interest in the maternity service dispute.—I am, etc.,

Sevenoaks, Nov. 16th. GORDON WARD.

SIR,—The present notification is too late to reduce the septic death rate in childbirth. It in its stead every expectant mother was *notified to the county medical officer*, and it was his duty to see that the living room and its surroundings were aseptic and that proper arrangements had been made for attendance on the mother, not only professional but domestic, the number of these cases in private practice would soon fall.

It would be no use passing a law to this effect unless arrangements were made for carrying out the order of the medical officer. He would require skilled assistant free from local influence and power to move the woman into hospital if his orders were neglected. How parents could be dealt with I don't know. Herein lies the real difficulty for expectant mothers often have very strong opinion and *the incidence of sepsis is too uncertain* to easily prove them wrong.—I am, etc.,

Silverton, near Exeter, Nov. 16th. O. CLAYTO JONES.

SIR,—One of the suggestions contained in Dr. Janet Campbell's report[1] is that medical practitioners should have the opportunity in difficult cases of calling to their aid a consulting obstetrician the responsibility for the payment of whose fee should be borne by the local authority. As one of the younger members of the profession practising in a purely industrial area I have often felt the need of expert assistance and advice and while I recognize that obstetrical operations are for the most part better performed in a living in hospital yet this is not always possible or practicable.

I may say that, as a member of the Leeds City Council and deputy chairman of the Health Committee I drew

[1] Report on Public Health and Medical Subjects (No. 25). Maternal Mortality by Janet M. Campbell, M.D., M.S. Issued by the Ministry of Health.

the attention of the Maternity and Child Welfare Committee, first, to the maternal mortality rate in the country, and secondly, to the suggestion quoted above The result has been that the following recommendations were made to the council and ratified on November 10th, and a copy is to be sent to all medical practitioners in the city

(*a*) That the fee paid to the consultant for his services be £3 3s for a consultation without operation, and £5 5s for a consultation with operation

(*b*) That the medical practitioner be required to fill up a form giving details of the case, including the nature of the emergency and the name of the consultant, and to transmit the same to the medical officer of health as soon after the consultation as possible

(*c*) That the claim for payment for services rendered be made on a special form to be supplied to each of the consultants on the staff of the maternity hospital

(*d*) That the patient be expected to contribute towards the cost of the services of the consultant according to means, each case to be judged on its merits

I, personally, should be very glad to see all city councils or local health authorities taking similar steps —I am, etc,

CYRIL J G EXLEY

Leeds, Nov 17th

PUERPERAL SEPSIS

SIR,—Referring to the leading article and to the report of the discussion on puerperal sepsis in the current issue of the JOURNAL, I beg to submit that in nine cases out of ten puerperal fever is a specific streptococcal infection over the onset of which neither the patient, the nurse, the midwife, nor the doctor has at present much control

Puerperal fever may occur after a miscarriage, after childbirth when the mother has not been attended by a doctor or midwife, and also when the utmost aseptic precautions have been taken and the most skilled attention been given It is probable that the causal streptococcus is already in the neighbourhood of the uterus before labour commences It is probable that, as in diphtheria and cerebro-spinal fever, many persons harbour the germ though they themselves are immune

In puerperal fever the streptococcus can be grown profusely on blood agar inoculated with a swab from the uterus, and in severe cases from blood cultures, from pleural effusions, and from metastatic abscesses It is a streptococcus which has definite characters by which it can be identified in cultures from the uterus, and (with the solitary exception of finding it in the cerebro-spinal fluid in a case of choice of pregnancy) I have not been able to find a streptococcus with similar cultural characteristics in any other infection, though I have been on the look-out for many years In about 10 per cent of cases of puerperal infection this streptococcus is not present, one finds faecal bacteria, streptococci of various sorts, and staphylococci as in ordinary septic wounds, and this occurs especially in cases where a difficult and tedious labour has necessitated much manipulation, such cases constitute real puerperal sepsis, and they are comparatively rare

The above remarks are based on my investigations on over 150 cases, most of which were admitted into the puerperal fever ward of the Birmingham and Midland Women's Hospital when I was bacteriologist there I believe that similar results have been obtained there up to the present time, and unless I am much deceived such results must appear wherever sufficient material is available for the investigator

Now if puerperal fever is a specific streptococcal infection surely it should be possible to prepare a specific antitoxin, a serum as efficient as, say, antidiphtheritic serum, and as readily available Or perhaps, if the specificity of the disease is generally admitted, a prophylactic vaccine may become available for those who wish to use it And if it became generally understood by the public and by the medical profession that the diagnosis of puerperal fever implied no blame to the doctor, midwife, or nurse, but that its prompt recognition averted its chief dangers, many of the difficulties in regard to its notification would disappear

If this letter leads to further investigation of this particular organism, its habitat and evolution, it is probable that facts may emerge which will enable us to reduce the incidence and mortality of puerperal fever —I am, etc,

LEONARD G J MACKEY.

Birmingham, Nov 16th

XANTHOMA AND XANTHOSIS

SIR,—In Professor M J Stewart's instructive and interesting article under the above title in the BRITISH MEDICAL JOURNAL for November 15th (p 893) the term "xanthosis" is used for local changes associated with the deposition of lipoid material (cholesterin esters, cholesterin) I would like to point out that this term 'xanthosis"—which, of course, literally means the condition of having become abnormally yellow—has already been applied to a yellow coloration of the skin (cutaneous xanthosis), especially of the palms of the hands and the soles of the feet, and in many cases the face also, which is not due to jaundice and is not necessarily (probably hardly ever) associated with any form of xanthoma

Such a xanthosis of the skin was described in 1904 (International Dermatological Congress) by C von Noorden in certain young patients suffering from diabetes mellitus Since then, however, its occurrence has been noted in other diseases and in apparently healthy persons The sclerotics are not at all, or only very slightly, coloured, and the skin never assumes the dark-greenish appearance that it does in cases of chronic obstructive jaundice

The pigment in question is supposed to belong to the class of lipochrome, lutein, xanthophyll, or carotin Cutaneous xanthosis is probably the same as Castellani's "ochronodermatosis" or "yellow disease," and has doubtless been described in France under the heading "xanthochromia cutis" Cachectic subjects seem to be more liable to cutaneous xanthosis than others, young wasting diabetics more than older well nourished diabetics, and poorly nourished children more than robust children, even when their respective diets are equally rich in carrots (cf H Salomon) The work on "carotinaemia" by Hess and Myers of New York (1919) was of special value in making generally known the possible effect of diets rich in carrot and other vegetables containing carotin on the coloration of the skin

At the October meeting of the Dermatological Section of the Royal Society of Medicine I showed a case of characteristic xanthosis of the hands and feet in a girl case of diabetes mellitus —I am, etc,

London, W, Nov 15th

CARBON MONOXIDE POISONING

SIR, — Dr Cunningham Affleck (BRITISH MEDICAL JOURNAL, November 1st, 1924, p 835) is wrong in saying that I agree with him "that poisons of an insidious nature are given off when certain fuel is burned," the fuel in question being coal gas There are traces of sulphuretted hydrogen in the fumes of a gas fire, and possibly traces of organic compounds similar in action to the tear gases used in the war, but these expend their energy in slightly irritating the respiratory membrane There is not the least evidence that they are absorbed and act as insidious poisons Dr Affleck says he can tell when carbon monoxide is present in small quantities, being possessed of an idiosyncrasy in regard to the action of the gas He must have a hard life of it, seeing that carbon monoxide is present in tobacco smoke! Dr Affleck had better lend himself out in place of the canary which is taken into mines in order to detect the presence of this gas, which to all men other than Dr Affleck is undetectable

The physiological facts concerning carbon monoxide are established, so are the facts concerning the harm done by breathing and living in a hot, stuffy atmosphere Scientific measurements alone can decide which of these agents is working the harm —I am, etc,

LEONARD HILL

London, N W, Nov 17th

SIR,—In your issue of November 15th (p 926) Dr Joel Lurd states that it is desirable that someone "should give us a clear explanation of what actually does occur" He also asks the question, "Is it possible that the transient combination of CO with haemoglobin damages the latter?" Whereas CO_2 and O both make feeble or loose chemical combinations with Hb, CO makes a much more stable combination It is not a *transient* combination Lurd and Stirling, in their *Textbook on Physiology*, state that

COHb has been found after many months by spectrum analysis When air containing CO is breathed by man it gradually displaces the O from the Hb volume for volume, and so prevents the oxygenation of the blood In one of the more severe cases of poisoning by CO, transfusion of blood is the only treatment —I am, etc

TONSILLECTOMY

SIR —I was very pleased to see Mr Steward's letter on tonsillectomy in your issue of November 8th (p 876) As an old general practitioner who had a good many cases of partial removal of the tonsils by the guillotine amongst my patients I can bear witness that the majority were quite successful Looking back, I do believe that in a small proportion of the cases enucleation would have been better There must be a good many of the *older practitioners and* operating surgeons who could give similar testimony — I am, etc,

Bath Nov 10 h J WIGMORE

SIR,—I have read with regret Mr F J Steward's letter in the BRITISH MEDICAL JOURNAL (November 8th, p 876), in which he comments upon the resolution unanimously passed by the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association, which reads as follows "That tonsillectomy by enucleation is the only efficient operation in dealing with tonsillar disease"

Mr Steward considers that this resolution is "idealistic and goes too far" He recognizes that tonsillectomy by enucleation is the most efficient operation, but he considers that tonsillotomy or partial removal may be equally so in some cases, and I gather that he even advocates it as *the operation of choice under certain conditions* One cannot but feel that such a view coming from so high and respected an authority must tend to encourage in *efficient tonsil surgery and to harden the unskilled operator* in his sins To those of us who are constantly meeting with the disastrous after results of such imperfect handiwork this is lamentable Surely it cannot be too strongly emphasized that partial removal of a tonsil is an unsound surgical procedure and that if a tonsil requires to be operated on at all the aim and object of the operation should be to remove the tonsil the whole tonsil and nothing but the tonsil and further that unless the operator has at his command the skill and facilities for ensuring this he should be strongly discouraged from attempting it

I am quite convinced that in a very large number of case an incomplete operation is worse than no operation at all, and that in those cases where such a procedure appears to have been efficacious the patient has got better in spite of the operation and not because of it

Mr Steward emphasizes the paucity of skilled operators There I concur, but I regard this as a difficulty which should, and must be, overcome I know from my own experience of certain districts that it can be But we must preach perfection—not complaisance To condone inefficiency is not the way to raise the standard of tonsil surgery, and I certainly consider the resolution in question absolutely sound Idealistic it may be but I believe it to stand for an ideal which is obtainable and which must be attained —I am, etc,

London W Nov 10th T TWISTINGTON HIGGINS

TREATMENT OF GOITRE BY IODINE

SIR,—The recent literature and correspondence on the above subject published in the JOURNAL have induced me to relate my own observations and experiences regarding the treatment of goitre, and, for the sake of brevity I will use the narrative form of statement

In the year 1889, whilst casting about for a remedy for Graves's disease, of which I had the fortune—good or bad—to have under my care a small group of cases, I found that syrup of iodide of iron, whilst of no use in the object of my search, was of decided benefit in ordinary goitre I forthwith adopted this form of treatment, pursuing it all through the years to the present time with marked success and, although I have unfortunately no regular statistics to quote, it is no exaggeration for me to say that out of some 400 cases of the disease more than half were cured and a considerable number of the remainder, some of whom discontinued the treatment, were more or less benefited Improvement was greatest and most rapid in the lateral enlargement the central part or the gland responding less readily to the treatment and this was especially the case when the swelling in this situation was of a smooth globular character for after prolonged efforts to cure, the condition was practically in *statu quo*

During my endeavours to relieve fastidious patients in their task of taking a somewhat disagreeable medicine I found that capsules containing the solid constituent of the syrup of iodide of iron were a comparative failure — in fact, more so than could be accounted for by the respective degrees of digestion and absorption of the two forms of drug employed—and from this I should infer that the combination of saccharine matter with the iodide gives rise to a special therapeutic effect which does not exist when they are taken separately This is a purely empirical fact and I allude to it without the least intention of dogmatism leaving it *to your more scientific readers to form* a better explanation than that given above

The results of my observations would lead me to be strongly impressed with the belief that syrup of iodide of iron is the ideal remedy for goitre, superior even to iodine itself or any of its derivatives A milder impression formed too late in my field of observation for any degree of certainty is a probable hereditary connexion between goitre and diabetes mellitus

By way of personal explanation I would like to say that although in the ordinary sense of the term I did not publish the above results, I spoke about the matter to my medical acquaintances, and went more fully into it at a meeting of the Warrington Medico-Ethical Society in the year 1911 during a discussion on a very able and interesting paper on the pathology and causation of thyroid enlargements by Dr C W Hutt at that time assistant medical officer of health for Warrington The reception of my views on this occasion however was not such as to encourage me in the direction of further publicity, and I allowed the subject to drop

I may add that the maximum success of this form of treatment depends to some extent upon several minor details and precautions, which I would readily furnish should my communication be of sufficient interest to any of your readers —I am etc,

Penketyn North Wales Nov 14th C W JOLLEPH M D

CROWNERS LAW

SIR,—With regard to the letter on coroner's law in your issue of November 8th may I suggest that the ignorant interference and the Lord High Executioner disregard of courtesy complained of is likely to persist so long as *non medical coroners are appointed*

A county council recently elected a non medical coroner for a county area Among the applicants were three who possessed both a legal and a medical qualification but the successful candidate was fortunate enough to have acted as deputy for his father the late coroner The new coroner will no doubt put forward a friend's name as his deputy and so these posts will be virtually closed to competition for many years The chief question put to candidates was whether they were "freeholders" this property qualification being necessary under the archaic Coroners Act of 1887

It is to be hoped that when the long overdue amending of this Act is carried out the British Medical Association will bring forward the desirability of candidates having both a legal and medical qualification—or at least a medical one At the present time the London County Council is the only one enlightened enough to demand both qualifications in its candidates though by law it must still insist on the successful candidate becoming a freeholder

Might I add for your correspondent's information that complaints concerning any coroner can be addressed to the Lord Chancellor, who though he has *not powers of appointment*, has powers to reprimand or remove a coroner"— I am, etc,

Salford Nov 11th E F HOARE

Obituary.

GEORGE ERNEST HASLIP, M.D.,

Late Treasurer of the British Medical Association

We had the sad duty last week of announcing the death of Dr. G. E. Haslip, which occurred on November 12th, at his house in London, after a long and painful illness, borne with great fortitude. It had been known to his friends for many months past that he was seriously ill and had undergone two severe operations. In July last his failing health compelled him to resign the post of Treasurer of the British Medical Association, which he had held with great ability and devotion for eight years.

George Ernest Haslip was born on August 7th, 1864, at Gravesend. He was the last surviving child of James Haslip. From Gravesend Proprietary School he went to the London Hospital, and obtained the M.R.C.S. Eng. and L.R.C.P. Lond. diplomas in 1887. After holding the posts of house surgeon and clinical assistant in the medical out-patient department at the London Hospital, he obtained the M.D. Brux. degree in 1889, and the D.P.H. of the English Conjoint Board in 1891. In the following year he began general practice in Suffolk Place, Pall Mall, and continued to work there until 1913, when he moved to St. James's Square. For more than thirty years he was medical officer to the Corps of Commissionaires, and in carrying out the duties of that appointment he never spared himself. He was most regular in his attendance at the corps headquarters in the Strand, and, in fact, seemed to regard that as the first duty in his busy day, when necessary he was assiduous in visiting the men in their homes. During those years Dr. Haslip built up a large private practice. He acted as medical adviser to several large insurance companies, and was physician to a number of the largest West End hotels.

Dr. Haslip was elected Treasurer of the British Medical Association in 1916. He had been President of the Metropolitan Counties Branch in 1913 and Vice-President of the Section of Medical Sociology in the same year, but he was not at that time at all widely known to members of the Association. He had, however, been Chairman of the Medical Insurance Agency since 1909, and in that office had shown his capacity as a financier. No one knew better than he that in becoming Treasurer of the Association at the beginning of the third year of the war he was undertaking an onerous task. The general financial position of the country was, of course, far from satisfactory, and the British Medical Association was suffering like other undertakings which had a commercial side. He gave much time and thought to the questions which came before him, and was in very frequent consultation with the then Financial Secretary, Mr. Guy Elliston. The unexpected death of Mr. Elliston in April, 1918, very greatly increased Dr. Haslip's responsibilities and anxieties, he did not shrink from giving his time very freely, and visited the office practically every day for many months preceding and following the armistice. Through all this trying time he never lost his contagious courage and high spirits, and came to be regarded with the greatest admiration and affection by all with whom he worked in the Central Office. It was a very great grief to them to notice the slow failure of his health, which began about eighteen months ago. The Association was never more fortunate in the choice of an officer than in getting Dr. Haslip for its Treasurer in 1916.

Dr. Haslip was one of the original members of the Consultative Council on Medical and Allied Services appointed in October, 1919, by the first Minister of Health, Dr. Addison, to advise the Ministry on such problems as the national development and extension of medical, nursing, and midwifery work. In the following year he was President of the Section of Medical Sociology at the Cambridge Annual Meeting of the British Medical Association, and introduced, with characteristic vigour and directness, the discussion on the future of medical practice, which was reported in full in our issue of July 10th, 1920. It was at that Annual Meeting, the first held since the war, that the President, Sir Clifford Allbutt, was presented with his portrait, by Sir William Orpen, which now hangs in the Fitzwilliam Museum, the proposal to open a fund for the portrait originated with Dr. Haslip, and his was the driving force behind all the arrangements.

Dr. Haslip had travelled much on the Continent and gained considerable first-hand knowledge of foreign spas and the methods of treatment carried out at each. He was a regular attendant at the Section of Balneology and Climatology of the Royal Society of Medicine, and for some years served on the council of the Section.

The first part of the funeral service was held at St. Martin's-in-the-Fields, Trafalgar Square, on Friday, November 14th. A very large gathering of friends nearly filled the church. The coffin was guarded by an escort from the Corps of Commissionaires. The British Medical Association was represented by the Chairman of the Representative Body, Dr. H. B. Brackenbury, the Chairman of Council, Dr. R. A. Bolam, the Treasurer, Mr. N. Bishop Harman, and the Deputy Chairman of the Representative Body, Dr. C. O. Hawthorne. Past and present members of Council included Lord Dawson, Sir Jenner Verrall, Dr. Charles Buttar (President of the Metropolitan Counties Branch), Dr. S. Morton Mackenzie, Mr. H. S. Souttar, Dr. F. W. Goodbody, Dr. Christine Murrell, and Dr. W. Johnson Smyth. Among the officers of Branches and members of the Representative Body were Dr. Comyns Berkeley (Treasurer, Metropolitan Counties Branch) and the Rev. S. D. Bhabha, M.D. (Greenwich and Deptford Division). The head office of the Association was represented by Dr. Alfred Cox (Medical Secretary), Mr. L. Ferris Scott (Financial Secretary and Business Manager), Dr. N. G. Horner (Assistant Editor of the *British Medical Journal*), Dr. G. C. Anderson (Deputy Medical Secretary), Dr. C. Courtenay Lord (Assistant Medical Secretary), together with many members of the headquarters' clerical staff. Wreaths were sent by the Council, members and staff, and by the Finance Department. The second part of the service was at Walton-on-the-Hill Church, Surrey, not far from "Amberdene," the country house where some of our friend's happiest days were spent.

Dr. Haslip married Anna, daughter of Maurice de Lemkauf, of Vienna, a privy councillor to the late Imperial Austrian Government, and President of the Agricultural and Shipping Exchange. She, with two daughters, survives him.

Sir Clifford Allbutt, who was President of the Association during the first five years of Dr. Haslip's tenure of the office of Treasurer, writes:

It was with something of a shock that I heard of the death of my dear friend Dr. Haslip. Of his long and painful illness we were only too well aware, but in its very fluctuations lingered some hopes of his amendment. It is hard to lose old friends whose days have been many, and whose course is run, but it is far harder to lose one so dear and so helpful to us all at an age which should have been the prime of life, in him of a most valuable life.

Before my acquaintance with Dr. Haslip I had often noticed that handsome alert man passing out of his house, then in Suffolk Place, and going swiftly on his way. Then came acquaintance, chiefly by the happy chance of two or three consultations in private practice, an association which soon ripened into affectionate regard. Then in time of war we were brought nearer and nearer to each other as we worked together on committees of public service. Again, as Dr. Macdonald of Taunton will remember, Haslip was a welcome guest indeed to us for the Annual Meeting of the British Medical Association in Cambridge. Our last meeting, for since then unfortunately I had failed to find him at home, was in the Association week at Portsmouth, when we stayed at the same hotel at Southsea. His stay was short, as his health was then far from good, but we had at least one long conversation which we did not due to think might be the last.

In every society Haslip's handling of affairs, and in every debate his influence, made themselves felt at once. His fine presence and keen, mobile, intellectual features had their effect in every word he said, words always of force and persuasiveness, words of a man of acute observation, large practical experience, and outstanding ability. His grip of finance was but one side of an all-round

mastery of affairs, and of a sound judgement and foresight in times of change and development. Yet sound and capable as he was, Haslip was not merely a man of cool and calculating mind, but also of an ardent temperament eager to see and to aim at the best possible purpose both in the present and the future. Business affairs and professional ideals were indeed but a part of Haslip's manysided life. He had a lively and cultivated interest in the fine arts, and enjoyed the intimate friendship of many of the foremost artists of his day.

Haslip's earnest diligence, his able management of the finances, and his other services to the British Medical Association, and not only these but also his good work for our profession at large, will no doubt be set forth in full in our JOURNAL. I must be content to celebrate our happy fortune in having enlisted, even for a comparatively short term of years, a Treasurer and Councillor of endowments so rare, of sympathies so wide and cultured, and of a personal ascendancy so beneficent. Our hearts are moved with deep sympathy with his widow and children in their untimely bereavement.

Lord DAWSON OF PENN writes:

Running through Haslip's work was an intense love of justice and right. His judgements were never cold, but always aglow with feeling. His outspoken opinions, with their occasional impetuous expression, were inspired by an abiding desire to see the helpful hand extended to the less fortunate in life's race.

The tale of his public service so little did he speak of it, was only known to the few. In the practice of our profession his success, in the best sense of the word, was great.

In this last illness the quality of the man stood forth—courage, first in struggle and then in dignified acceptance, gratitude, tender thought of others to the end. His memory will live and help us.

Photograph by] [Lafayette, Ltd.

G. E. HASLIP, M.D.

LATE TREASURER OF THE BRITISH MEDICAL ASSOCIATION.

Sir HUMPHRY ROLLESTON, Bt., K.C.B., President of the Royal College of Physicians, writes:

G. E. Haslip's death, not unexpected by those who knew the nature of his long illness, removes a striking personality who did much for his fellows in our profession. Much occupied in a busy general practice it is indeed remarkable how he found time for all the work outside the daily round that he accomplished. A good man of business with wide views and imagination, his service as Honorary Treasurer of the British Medical Association during a period of great activity and importance will receive the high appreciation they deserve from others more closely connected with this side of his activities. In addition he took a keen interest in charitable schemes for the poor and needy in the medical world, and with this end in view advocated changes in the Royal Medical Benevolent Fund and Lyon's Clothing Fund. Having known him for more than twenty years, I had learnt to value his enthusiastic, high-minded, and attractive character, and to admire his grip of affairs and public spirited devotion to work outside the scope of medical practice but concerning the well being of those in and connected with his profession.

Dr. P. V. BOLAM, Chairman of Council, writes:

George Ernest Haslip's work for the British Medical Association was in many ways remarkable. It is given to few medical men to obtain that mastery of business detail which commands success in organization, to reveal still to exhibit great aptitude in matters of finance. Of this select number was Haslip. He came to be Treasurer in a time of financial anxiety and stringency for the Association, and in spite of ever-expanding activities and responsibilities its affairs were guided on sound and prosperous lines. Throughout the years of his office he did invaluable and enduring work for the interests of the Association in hours snatched from the brief leisure of a busy professional life. One of his last official acts was the signing, or perhaps the largest cheque so far drawn on our account—for the purchase of our new house, in the negotiations for which his personal influence and acumen were conspicuous.

In medico-political affairs it would happen on occasion that Haslip took a view at variance with that of the majority. Yet he earned general respect for his fearless advocacy of a minority cause, and admiration for his loyal adherence to a general decision once taken. Whilst quick and keen in business matters, shrewd in judgement of men and skilled in affairs, Haslip radiated sympathy and inspired affection. Those to whom the privilege of his friendship was given recall the many deeds of kindness, the ready appreciation of another's viewpoint, the impartial tact—all of a generous and warm and generous nature. Through the last long months of suffering and uncertainty he showed that Heraclean cheerfulness and courage which led us to cherish till the end a hope heartfelt but unfulfilled.

Dr. J. A. MACDONALD, late Chairman of Council, writes:

It was with deep grief that I heard of the death of Dr. Haslip, yet I could not regret that the long-continued suffering which he had endured with such courage was at last at an end. Among the many friends I have made during my connexion with the administration of the British Medical Association there were few dearer or who interested me so much as Dr. Haslip. In him a mind with keen business instincts, the impulses of an artistic nature, and dominated by an invincible honesty constituted a personality which was very attractive and constantly interesting. In his invaluable work for the Association we were not infrequently at variance, and he never failed to support his opinion and explain his criticism in forceful terms. Yet his opposition and criticism were never cavilling, and roused in me nothing but respect and admiration, as his actions and speech so patently had their origin in honest conviction. But it was at home or with friends at dinner that the lovable nature of Dr. Haslip had its full expression. His cheery optimism, his genial humour, and his charity of outlook for others were a constant joy to those who were with him. In this respect I can never forget one week I spent with him as guests of Sir Clifford Allbutt at Cambridge. The intercourse with two such men will ever

remain a gem in my memory Among the many—far too many—friends who have passed away there are very few whose loss I shall regret so much as that of Dr Haslip

JOHN BENJAMIN HELLIER, M D,

Consulting Obstetrical Physician to Leeds General Infirmary

It is with great regret that we have to record the death, in his 72nd year, of Dr J B Hellier of Leeds, which took place on November 8th Until a short time ago Dr Hellier was in active consulting practice Of late his health had been manifestly failing and his gait getting weaker, but in spite of this he maintained a spirit of great cheerfulness to the end, which came rather rapidly

The connexion of Dr Hellier with the Leeds School has been a long and remarkably creditable one He was a student of Leeds and University College Hospital, London, receiving the diploma M R C S in 1875 When in 1876 he graduated M B at the University of London with first class honours in medicine he brought credit to his school by being awarded the University scholarship and the Gold Medal in Obstetrics He proceeded M D in 1878 He acted as demonstrator in anatomy and subsequently as lecturer in materia medica, in which department he was instrumental in founding the museum. He was for some time in general practice, but obstetrics and gynæcology were his chief interest in life, and his successive elections to the lectureship in gynæcology and to the professorship in obstetrics, associated with his appointment as gynæcologist to the General Infirmary, gave him full scope for his energies In the year 1918, in accordance with the rules of these two institutions, he became a member of the consulting staff of the infirmary and resigned the chair of obstetrics, the University marking its appreciation of his long services by conferring upon him the title of emeritus professor He was a vice-president of the Section of Gynæcology and Obstetrics of the Annual Meeting of the British Medical Association at Liverpool in 1912

Photograph by [*Rosemont (Leeds)*

J B Hellier, M D

During the whole of Dr Hellier's connexion with the Leeds University and Infirmary he manifested in a remarkable degree an unswerving and conscientious regard for the welfare of the school and of the students Himself an admirable and impressive lecturer, he set a high value upon those lectures which were the result of careful thought and which consisted of something more than the mere vocalization of facts, and those who were privileged to listen to him soon came to understand that there were many things which could be learned from lectures which could not be learned from books alone The members of the Leeds and West Riding Medico-Chirurgical Society will call to mind his many valuable contributions to its proceedings Especially does the writer of this notice remember his admirable presidential address on the medical curriculum, its deliberate and thoughtful presentation illuminated with flashes of real humour Indeed, anyone who should try to form an appreciation of Hellier's character without regard to his keen sense of humour would very properly fail His nature was genial and kindly, and his humour was equally so, he never said an unkind word to anyone The welfare of a medical school depends not only upon those features of its teaching and opportunities for research which lie upon the surface and can be seen by all, but upon the conscientious discharge by some members of the staff of those routine duties—sometimes almost regarded as drudgeries—which carry with them no recognition and no immediate reward He was the author of *Infancy and Infant Rearing*, an article on "Fistulæ in the female genital tract" in Eden and Lockyer's *System of Gynæcology*, and various publications in medical periodicals

At the annual dinner of the past and present students of the Leeds School of Medicine, held on November 14th, Mr J A Coupland, in responding to the toast of the staff, made a most touching reference to the loss which the school and the profession had sustained, and his words found a ready response in the hearts of all who were present Dr Hellier will be greatly missed, for he stood high in the respect of his colleagues and of his students, but he leaves behind him a record of work and an example which will live

JOHN F W TATHAM,

M.A M D F.R.C P

Formerly Superintendent of Vital Statistics

We regret to record the death of Dr John Tatham, which occurred at the age of 81, at his house in Oxted, Surrey, where he was living in retirement after a long period of important public service

His first qualification, obtained in 1867, was the L R F P S Glasg In 1881 he graduated in medicine and arts at Trinity College, Dublin, and proceeded M D two years later He was elected F R C P Lond in 1893 and F R C P I in 1906

He obtained the diploma in public health of the University of Cambridge so long ago as 1876, and his life's work centred round that subject His principal appointments up to 1893 were the medical officership of health for Salford, and then for Manchester, and his work there, in relation especially to vital statistics, was so good that when Dr Ogle retired from the position of superintendent of vital statistics at the General Register Office, Somerset House, Dr Tatham was appointed in his place in 1893 He held that post with credit and distinction for sixteen years, and in that way was responsible for two of the decennial supplements which, begun by Dr Farr, have ever since been looked on as the most important sources of information as to the causes and course of mortality, available to all who wish to study the subject As medical officer of health, Dr Tatham had issued life tables for Manchester, and during his tenure of office at Somerset House he devoted special attention to occupational mortality Such statistics, though only records of deaths which have already taken place, constitute the basis of subsequent preventive and ameliorative work

Dr Tatham by no means confined himself to his strictly

official duties When in Manchester he was lecturer on hygiene at Owens College, and later on he was chairman of the Statistical Committee of the Imperial Research Fund, and was a member of the Privy Council Committee on Physical Degeneration Even after his retirement he could not be idle, and the writer of this notice had the pleasure of meeting him in clerical garb a few years ago, he having taken up such service, for which he was excellently qualified, in connexion with the war Dr Tatham was a man of fine presence and address and a good speaker He was a university examiner in public health and a past-president of the Society of Epidemiology He was entertained to a public dinner both on the occasion of his leaving Manchester and on retiring from his appointment at Somerset House At Manchester his distinguished successor was Dr James Niven, who now also has retired So generation succeeds generation and Dr Tatham, after a long and full life, has gone to his rest respected and loved by all who knew him

M G HANNAY, M D,

Dean of the London School of Dermatology

British dermatology has suffered a severe loss in the death, which took place on October 24th, of Dr Maurice Gilbert Hannay Dr Hannay received his medical education at Charing Cross Hospital and at Edinburgh Obtaining the London Conjoint qualification in 1900, he took up the study of skin diseases, being clinical assistant in the skin departments at Charing Cross Hospital and the Victoria Hospital for Children and later at the Royal Infirmary, Edinburgh He also studied at the St Louis Hospital, Paris Before the war he was in general practice in the South of England, but gave this up to take a temporary commission in the R A M C After seeing active service in France he settled in London as a consulting dermatologist, and was appointed assistant physician to St John's Hospital for Diseases of the Skin, Leicester Square He had, in 1907, taken the degree of M D Brux, and in 1919 was elected to the Fellowship of the Royal College of Physicians of Edinburgh of which College he had previously been a member In 1921 he obtained the M R C P Lond diploma

Dr Hannay took a large share in the formation of the London School of Dermatology in 1922 The arrangement by which the staff of St John's Hospital combined with the teachers in dermatology at the twelve London teaching hospitals to give a systematic course in dermatology at St John's Hospital seemed at first difficult of achievement *It was, however, finally brought to a satisfactory conclusion,* largely by Dr Hannay's enthusiasm and by his willingness to allow two appointments to the staff of the hospital to be made over his head He was appointed first dean of the school, and carried out the difficult functions of the post with great diligence and tact

Dr Hannay was the author of several papers on dermatological subjects, the most recent being a very careful study of urticaria pigmentosa in adults, which he read before the British Association of Dermatology and Syphilology in July last

JOHN GORDON BLACK, M D,

Harrogate

We regret to announce the death of Dr John Gordon Black at his residence in Harrogate on November 11th Dr Black was the doyen of the Harrogate medical profession He was born in January 1843 at Consett co Durham, where his father, Lancelot Black, was the first manager of the Consett Ironworks His schooldays at Newcastle-on-Tyne Academy were passed under the head mastership of Dr Bruce—*a man of sterling character and erudition* He did not start the study of medicine until the age of 21, when he entered the Newcastle Medical School He obtained the M D Lond degree in 1871. After four years of strenuous work in general practice at Newcastle on Tyne, he had *a serious breakdown in health,* but a voyage to Australia restored him On his return to England Dr Black settled at Rothbury, Northumberland, in which place he spent some of the happiest years of his life In 1881 he moved to Harrogate and made a special study of the practice of balneology He wrote monographs on Harrogate and on the subject of rheumatism gout and allied affections, he was much interested also in gynaecology

Dr Black was at one time vice president of the Yorkshire Branch of the British Medical Association He founded and became president of the Harrogate Medical Society, and was a vice president of the Leeds and West Riding Medico-Chirurgical Society A keen chess player he started the Harrogate Chess Club, and played a good game up to the last He was also enthusiastic about golf, and gave a handsome challenge cup to stimulate interest in the game amongst the members of the Harrogate Medical Society He was a good friend to the town of his adoption and was held in great respect by his fellow practitioner, who recognized in him a large hearted, generous and kind colleague He was twice married, and is survived by a widow and one son and one daughter, children of the first marriage

THE LATE DR H C MACTIER

Dr T Connell Craig writes Throughout a quarter of a century Dr H C Mactier (of whom an obituary notice appeared in the *Journal* of November 8th) was in close touch at many points with the professional life of Wolverhampton, as consultant, general practitioner, and anaesthetist He took a very active interest in the introduction of the National Health Insurance Act, and when the Panel Committee was first formed he became its secretary, holding this position until his death He was always willing, and generally able, to give valuable advice and help in all matters connected with the South Stafford hire Division and he will be very greatly missed The Panel Committee also owes him a great debt of gratitude for the zeal he displayed as its secretary and for the wide and intimate knowledge he possessed of the National Health Insurance Acts and the medical regulations she embody It will be very difficult to fill his place adequately in either of these respects Although he came in personal contact with almost every practitioner in the neighbourhood and there were many occasions on which friction might easily have occurred yet he remained to the end the friend and trusted adviser of them all The esteem and affection in which he was held was shown very plainly by the large and representative gathering which met to do honour to his memory

Dr Frederick John Paley of Hove died on November 12th at the Royal Sussex County Hospital following an operation aged 65 He was the son of the late Professor F A Paley of Cambridge, and was educated at The Oratory, Edgbaston, and at St Bartholomew's Hospital He graduated M B Lond in 1883 and M D four years later, he also took the diplomas of L R C P and M R C S. in 1883 After serving as resident medical officer at St George's Retreat Burgess Hill and house-surgeon to the Women's Hospital Brighton and the Royal Sussex County Hospital, he began practice in Brighton in 1890 He had served as secretary member of council, and president of the Brighton, Hove, and Sussex Medico-Chirurgical Society, and was senior surgeon to the Royal Sussex County Hospital During the war he served with the rank of lieutenant-colonel R A M C, as commandant of the 2nd Eastern General Hospital For his services to Catholic institutions he was created a Knight of the Papal Order of St Gregory, one of the highest distinctions bestowed by the Pope Dr Paley was a member of the Brighton Division of the British Medical Association and his death is keenly felt by many medical colleagues

Dr Charles Turner Standring of Broadway Worcestershire died on November 8th aged 59 He was born in Kent the sixth son of the late Mr John Standring and was educated at Blackheath School and King's College London He took the diploma of L S A in 1891 After serving as house-surgeon to the Shrewsbury Hospital and as assistant in various parts of the country he settled in Broadway, where he continued to practise until his death

He was at one time a member of the parish council, he also acted as instructor to ambulance classes During the war he was on the staff of the Farncombe and Abbey Manor Hospitals, and was also medical officer for the Belgian refugees Dr Standring was a great sportsman and took an active part in most games, he was founder of the Broadway Golf Club started in 1896, of which he was first secretary, and continued to hold that post till 1921 He was a member of the Worcestershire Division of the British Medical Association In the words of a colleague "He was a cheery soul and made an extraordinary number of friends" He is survived by a daughter There was a large gathering of friends and patients at the memorial service

---

Dr Robert Russell Harper, who died at the beginning of October, in his 71st year, was educated at St Thomas's Hospital, where he obtained the diplomas of M R C S, L R C P, and L S A in 1875 He practised first at Holbeach, in Lincolnshire, and later at Hampstead During the war he was attached to No 1 Birmingham War Hospital, and later became medical superintendent of the Pensioners Hospital in that city Whilst a student he helped to organize the first inter-hospital Rugby competition

---

We regret to record the death, on October 30th, of Dr Henry Christopher Lamport Dr Lamport obtained the degrees of M B and C M at Edinburgh, and was in private practice for many years subsequently, until ill health caused his retirement He was for twenty years one of the honorary medical staff of the Royal Lancaster Infirmary He had been a member of the 5th Lancaster Volunteer Artillery from 1890, and during the war served with the R A M C (T F), having charge of several hospitals and attaining to the rank of lieutenant-colonel Since the war he had acted as honorary surgeon to the St John Ambulance movement, becoming an honorary associate of the Order of the Hospital of St John of Jerusalem in England The funeral was attended by many friends and by representatives of the public bodies with which Dr Lamport was associated He was held in high esteem by all who came in contact with him, and those who knew him best will remember his unfailing cheerfulness and patience through a long and trying illness

---

Dr Peter Thomson, medical superintendent of the Ochil Hills Sanatorium, Kinross-shire died on October 30th He was a native of Dumbarton, and received his medical education at the University of Glasgow, where he graduated M A in 1887, B Sc in 1900, and M B C M in 1893, he took the D P H Edin in 1918 After practising for a time on the south side of Glasgow he became assistant to the professor of anatomy at the Anderson College of Medicine, Professor A M Buchanan, who in the third edition of his *Manual of Anatomy* acknowledges with gratitude the valuable assistance rendered by his demonstrator, Dr Peter Thomson, in preparing the edition for the press He was formerly assistant tuberculosis officer for Glasgow, and was appointed to be superintendent of the Ochil Hills Sanatorium three years ago

---

Dr Percy Slack died at his residence in Rotherham on November 6th He was the son of a Wesleyan Methodist minister, and received his education at Sheffield and St Mary's Hospital He took the diploma of L S A in 1893 and the Scottish triple qualification in 1894 He was honorary radiologist to the Rotherham Hospital, honorary secretary of the Local Medical and Panel Committee, and a member of the Rotherham Division of the British Medical Association

---

We much regret to announce the death of Dr W B Crawford Treasure of Cardiff, until recently a member of the Council of the British Medical Association formerly President of the South Wales and Monmouthshire Branch, and Representative and Chairman of the Cardiff Division We hope to publish an obituary notice in an early issue

Medico-Legal.

THE DISPENSING OF A PRESCRIPTION

The jury failed to agree in a case before Lord Darling in the King's Bench Division on November 17th, when negligence in compounding a medical prescription was alleged by Mr Russell Boyd and his son, Geoffrey Russell Boyd, of Roehampton, against Messrs Savory and Moore, Ltd, chemists, of New Bond Street

The plaintiffs said that Mr Geoffrey Boyd, who was now 22 years of age, was subject to epileptic fits, and Dr Henry Head on May 30th, 1922, prescribed for him a medicine to contain one grain and a half of luminal sodium The defendants made up the medicine from the prescription on various dates between May 30th, 1922, and March, 1923, but instead of putting in one grain and a half of the luminal sodium they used only half a grain

Dr Head, asked by counsel Can you say that the absence of one grain of luminal sodium each night for ten months has had any material effect on the course and progress of epilepsy?—replied, No certainly not

Dr C M Hinds Howell agreed, adding that half a grain was quite a common dose to prescribe

Sir William Willcox answered two questions put by the jury Is there any cure for epilepsy recognized by the medical profession?—No cure

Would continued use of drugs produce cerebral softening?—The continued use of a drug like luminal sodium in large doses certainly does cause mental degeneration

Defendants denied negligence and said they acted reasonably in reading the prescription They also said that the younger plaintiff suffered no damage

Lord Darling held that there was no evidence which would justify the jury in returning a verdict for the plaintiffs, for the reason that the evidence called for the plaintiffs themselves was that it was impossible to say that the absence of the one grain of luminal sodium had produced any ill effects whatever Therefore he considered it his duty to enter judgement for the defendants with costs

Universities and Colleges

UNIVERSITY OF GLASGOW

The following degrees were conferred on November 15th

M D—*Katherine O Robertson A Anderson Alice Cox (in absentia)*
M B C M B—Isdale R Taylor
B Sc (*in Public Health*)—J Wylie (*in absentia*)

* With commendation

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council was held on November 13th, with the President Sir John Bland Sutton, in the chair The death of Mr J Hammond Morgan, C V O past member of the Council was reported and a vote of condolence was passed Diplomas of Membership were granted to 245 candidates (The list was printed with report of the comitia of the Royal College of Physicians, November 8th, p 879) Mr W G Spencer was re-elected a member of the Committee of Management

A report transmitted from the Royal College of Physicians, of the Committee of Management regarding institutions recognized for courses of instruction for the several special diplomas was received and adopted

The Services.

COMMISSIONS IN THE R A M C

The War Office announces that not fewer than twenty commissions in the Royal Army Medical Corps will be granted to successful candidates in an examination to be held in London on January 28th next Applications to compete must be made not later than January 18th and in the meantime a full statement of the duties and emoluments of the service can be had on written application to the Under Secretary of State (A M D 1), the War Office, Whitehall, London S W 1

DEATHS IN THE SERVICES

Colonel William Lewis Gray, C M G Army Medical Service (ret), died of pneumonia at North Holt Hythe on November 3rd aged 60 He was born in London on July 17th, 1864, the second son of the late Alexander Gray, M D, of Selby, and was educated at Glasgow, where he graduated as M B and C M, with commendation, in 1885 and at Edinburgh, where he took the B Sc in Public Health in 1888 Entering the army as surgeon on February 5th, 1887, he attained the rank of lieutenant-colonel on August 2nd, 1911, and colonel in the long promotion list of March 1st, 1915, retiring on August 10th, 1919 He served on the Anglo-Siamese Boundary Commission of 1889-90, on the Kienglung Chienghun mission of 1890-91, in the Chitral campaign on the North-West Frontier of India in 1895, when he took part in the relief of Chitral (medal and clasp), in South Africa in 1900-01 in operations in the Transvaal, Orange River Colony, and Cape Colony (mentioned in dispatches, *London Gazette*, April 16th 1901, Queen's medal with four clasps) and in the war of 1914-18 (mentioned in dispatches, *London Gazette* June 15th, 1916 and January 4th, 1917), and received the C M G in 1917 In 1897 he married Janet, daughter of Thomas Orr, accountant, London, but leaves no children

QUERIES AND ANSWERS.

Income Tax

Motor Car Replacement

"B A S" has claimed to deduct the difference between the cost price of his car and the amount for which it has been sold The Inspector of taxes proposes to restrict the allowance to the excess of the cost of a similar car *at the date of sale* over the amount realized

*** Neither method is correct The Income Tax Acts do not permit the deduction of sums representing loss of capital, with the exception of the depreciation allowance, which does not apply to professional earnings The deduction to which "B A S" is entitled is the excess of the cost of a new car bought to replace the old one over the amount received by the sale of the latter, subject to the stipulation that the allowance shall not include any amount in respect of further capital outlay When prices are falling the system works against the practitioner, but that result necessarily follows from the existing statutory regulations

Glebe Rent and Ground Rent

"Glebe' owns a house the income tax on which is deducted from the rent paid to him, out of that rent he pays £5 a year glebe rent and £5 a year ground rent

*** The position is as follows His tenant is not entitled to deduct a greater amount of tax than that applicable to the rent —that is, he should deduct the tax on £50 only and not the full tax on £52 10s, the amount of the assessment "Glebe" is entitled to deduct tax in his turn from both the glebe rent and the ground rent provided that they are not separately assessed, and this is not alleged The statutory authority for that deduction is in the Income Tax Act, 1918, Schedule A, No 8, Rule 4, which states that "where any hereditaments are subject to the payment of any annual sum a landlord from whom tax is deductible shall be entitled on making such payment to deduct and retain thereout so much of the said tax as represents the rate or rates of income tax in force during the period through which the said payment was accruing due" It will be noticed that the right is to deduct "on payment" it does not extend to cover a claim to recoupment for past periods for which payment has been made

Dominion Income Tax Relief

"J S" writes My total gross income is as follows Professional income assessed at £200, taxed dividends £86, dividends from South Africa £324, total £610 Colonial income tax was paid on the £324 dividends, but has not been deducted in arriving at that amount

*** His liability is as follows.

	£	£ s d
Total income	610	
Deduct earned income relief ...	20	
	590	
Deduct personal allowance	135	
Taxable income	455	
Of which £275 is chargeable at 2s 3d	=	25 6 3
And the balance £230 is chargeable at 4s 6d	=	51 15 0
		77 1 3
Of which there has been accounted for by deduction £85 at 4s 6d		19 7 0
Leaving a balance of		57 14 3

"J S" is, however, entitled to a further allowance in respect of Dominion income tax equal to £324 at the Colonial rate, or at half his appropriate rate, whichever be the less, the appropriate rate is approximately 3s 5d.

Epileptiform Fits

Dr D S C Reid (Blackburn) writes in reply to "H C B" (November 8th, p 883) For his case of epileptiform fits I should recommend him to try small doses of chloretone

Pernicious Vomiting

Dr A Blaiston (Brixham, Devon) writes with reference to Dr Crawford Lundie's letter, November 15th (p 929) I have had great success in cases of pernicious vomiting in pregnancy by putting patients on rectal feeding and small doses of morphine hypodermically

LETTERS, NOTES ETC

Puerperal Pyrexia

Dr Claude Wilson (Tunbridge Wells) writes As you invite discussion, and as there seems to be a general agreement that a temperature of 102° F —or even 100° F (Dr Dudfield, British Medical Journal, November 15th, p 900)—lasting for over twenty four hours should be regarded as indicating a septic cause, I venture to ask the views of those with large experience on a case which occurred in my practice many years ago, which caused me much concern at the time, and which has never since been out of my mental vision when considering the question of puerperal pyrexia The temperature rose a day or two after childbirth and lasted for three or four days, reaching a maximum of nearly 105° F The patient, though restless and sleepless, and with a rapid pulse, was at no time desperately ill, and I could find no indication of local sepsis The late Dr Braxton Hicks was called in, confirmed the absence of local infection, pronounced the case one of incipient puerperal mania, and prescribed 40 grains of antipyrin with 20 grains of bromide The patient slept for about twelve hours, woke up with a normal temperature, and made an uninterrupted recovery

Future of Tropical Medicine and Hygiene

Dr Andrew Balfour, C M G (London School of Hygiene and Tropical Medicine) writes In the abstract of my address to Anderson College on the above subject which you were good enough to publish in the British Medical Journal for November 15th, I notice that I am reported as saying that the Libyan race is in danger of extinction owing to the influence of civilization As this statement is almost certain to be called in question, I think it well to explain that what I said has not been quite correctly transcribed I spoke about Libya solely from the point of view of the absence of syphilis, and my reference to the influence of civilization was confined to those islands of Melanesia, notably the Solomons, where as noted by Dr Rivers in his interesting *Essays on the Depopulation of Melanesia*, decay has overtaken the inhabitants

Modified Whitehead Operation

Sir John O'Conor, K B E (Buenos Aires), writes The recent correspondence anent the treatment of haemorrhoids by injection prompted my asking the hospital registrar to make an extract of the time occupied in the last 100 cases operated upon by me by above method Result 3 in four minutes, 6 in five, 32 in six 16 in seven, 17 in eight 11 in nine, 6 in ten, 2 in eleven, in association with fistula, 5 in twelve, 1 in sixteen, and 1 in seventeen To date there has not been an instance of any post operative complication reported This series have been operated on since my article on radical cure was published in the British Medical Journal, May 13th, 1922 (p 759)

United Hospitals Winter Sports Club

Dr J Duncan Lall (Maidenhead) asks to be allowed once again to bring the United Hospitals Winter Sports Club (of which he is hon secretary) to the notice of our readers The club was founded to obtain advantageous terms at winter sports resorts and to encourage these sports amongst past and present students of all recognized medical schools in the United Kingdom The season the Lord Dawson Cup for skiing will be competed for early in January at Grindelwald, Bernese Oberland, but for those members who prefer the Engadine a second hotel (Hotel Waldhaus, Sils Maria) has undertaken to assist members in many ways Full particulars can be obtained from the managers of these two hotels

Neutralization of Insulin before Injection

Colonel G F Rowcroft (Coonoor, South India) writes with reference to the article by Dr Stilwell in our issue of September 13th (p 465), in which it is stated that a 6 per cent solution of sodium bicarbonate with 3 per cent tricresol, sterilized by filtration through a Berkefeld filter was used Colonel Rowcroft asks, Is this filtration necessary? Is not the tricresol sufficient? or would it not suffice to boil the sodium bicarbonate solution? The filtration process (he adds) seems to add unnecessary difficulties and expense to the administration of insulin

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 34, 35, 38 and 39 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 36 and 37

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 195

Medicine.

394 Vagotonia.

H L HEIMANN (*Med Journ of South Africa*, September, 1924, p 28) records two cases of vagotonia occurring in big, energetic men The first patient, aged 67, retired had complained for eighteen months of attacks of giddiness preceded by sweating and followed by nausea headache, and at times unconsciousness suggestive of heart block Epilepsy and the Stokes Adams syndrome were negatived by the absence of nervous manifestations during the attacks Electrocardiographic examination disclosed no abnormality, but during the coughing and deep inspiration there was slowing of the pulse Under graduated gentle exercise, avoidance of tobacco, removal of septic teeth, and dieting to prevent gastric distension, together with tinct belladonnae mv t d s, the attacks ceased The second patient, aged 52, complained of breathlessness and inability to lie down His lips were blue but there was no distension of the jugulars and no sign of cardiac, pulmonary, or hepatic abnormality either on physical or x ray examination It was concluded that the vagus was hypertonic, thus causing bronchial spasm and breathlessness, and accounting for the low blood pressure, 120/65 As this patient had spent most of an energetic life in the blazing sun near Nairobi it was suggested that the condition was secondary to suprarenal exhaustion due to a combination of hard work and excessive exposure to sunlight Improvement followed residence at a lower altitude, dental treatment dieting, and medicine as in the first case, with the administration of suprarenal gland cryst gr j, and ext thyroid sicc gr ½

395 Pseudo malarial Attacks in Typhoid Fever

G CAUSSADE and H LE PASLE (*Presse méd*, September 13th 1924, p 749) record six cases of the pseudo malarial type of fever, first described by Jaccoud in 1884, which occurs during defervescence or at the beginning of convalescence from typhoid In most cases the attacks are quotidian, but in rare instances are bi quotidian or tertian The attacks may be of short moderate, or long duration The end of an attack is marked by sweating, and a fall of temperature which is sometimes very sudden and as low as 95 4° F, but occasionally the temperature may remain above normal at the end of an attack and oscillate for some days about the level of 100 4° Polyuria is frequent at the end of the attack and may be as much as 5 pints in the twenty four hours for several days Recovery is the rule In the diagnosis cholecystitis pyelonephritis, and a relapse of malaria must be excluded If malaria is present quinine will have a successful effect upon the attack, and all doubt will be removed by finding the malarial parasite in the blood

396 Clinical Manifestations of Vitamin Deficiency

C E BLOCH (*Ugeskrift for Laeger*, October 16th, 1924, p 783) has treated 70 cases of xerophthalmia, some having been under observation for a considerable time before the xerophthalmia developed. In most of these cases the diet had long been deficient in vitamin A, but it had not been completely free from this vitamin except in a few cases, for even centrifugalized and butter milk may contain some vitamin A A close study of all these cases led to the conclusion that the xerophthalmia depended not only on an inadequate supply and faulty assimilation of vitamin A, but also on two other factors—namely growth of the child and infectious diseases It would seem that both these factors entail an abnormally great consumption of vitamin A and that xerophthalmia and other signs of vitamin A deficiency are not merely the outcome of an inadequate supply of this vitamin, but also of a temporarily exaggerated need on the part of the organism for such vitamin While xerophthalmia is pathognomonic of vitamin A deficiency arrest of development, loss of weight, reduced mental and bodily vitality, and impaired immunity to infections are sequels not peculiar to a shortage of vitamin A The author records in detail two cases in which deficiency of vitamin A in children seemed to depend not so much on an inadequate supply of vitamin A as on its inadequate absorption This was due to disease of the liver, as indicated by jaundice In the second case the tendency to develop xerophthalmia was further aggravated by the development of pneumonia This observation, that vitamin A deficiency may depend on inadequate absorption of an adequate supply of vitamin A, led the author to give cod liver oil by subcutaneous injection in five cases of xerophthalmia The oil was sterilized in boiling water, and first 0 5 c cm and later 1 c cm were injected every day All these patients recovered but as they were also given a plentiful supply of vitamin A by the mouth the author cannot give irrefutable evidence in support of his definite impression that these subcutaneous injections were very beneficial At all events they were painless for the first few days, but after four to eight days they provoked redness and tenderness with general malaise and an evening temperature between 99 and 102° F In no case did abscesses form, and the benefits obtained more than compensated for the discomforts inflicted

397 Post scarlatinal Eruptions

J KLEEBERG (*Zeit f Kinderheilk* August 30th 1924 p 577) states that hitherto post scarlatinal eruptions have been regarded as very rare His own experience however has been very different, as he has observed them in 42 out of 115 cases under treatment in the department for infectious diseases of the Rudolf Virchow Hospital in Berlin between September 1923 and May, 1924 Age and sex were of no etiological significance as the rashes were seen alike among infants and persons of 60 They were commonest in obese persons The eruption usually appeared at the end or middle of the second week, and usually lasted five to eight days The buttocks and patellae showed the first lesions and the legs and trunk were next affected but there was no regularity in the order of their involvement The distribution of the lesions was symmetrical If the eruption first appeared on only one arm or leg it became bilateral the next day The favourite sites were the buttocks patellae femoral triangle and calves The arms were rarely affected and the face neck and chest always remained free No mucous membrane rash occurred nor sore throat The initial lesions consisted of discrete punctate red papules, which, after six to eight hours, increased in size and number The peripheral parts of the lesions desquamated freely even when desquamation on the trunk had not begun or had not finished The general condition did not appear to be affected There was no rise of temperature or digestive disturbance Examination of the blood showed a normal or slightly increased eosinophil count and a slight lymphocytosis Post scarlatinal eruptions bear no relation to the primary rash of scarlet fever as regards their duration, extent, or intensity

Surgery.

398 A New Treatment for Surgical Tuberculosis

A. VAUDREMER (*Presse méd*, October 8th 1924, p 801) refers to his discovery (with Louis Martin) in 1900 of a tuberculous poison other than tuberculin, rapidly fatal to guinea pigs when injected into the arachnoid or the peritoneum Its toxicity varies with different strains among fourteen strains they found one which was very virulent The toxin is not eliminated by the bacilli unless they are from old cultures granular still acid resistant but surrounded by bodies which stain with methylene blue Bezançon and Philibert published an important study of these bodies (*Revue de la Tuberculose* July, 1914) Vaudremer describes the experiments which have led him to conclude that tuberculin has a sensitizing action in men and animals He holds that tuberculin should not be present in bacilli used for therapeutic purposes, and that the bacilli should be deprived of their acid resistance Both may be removed by the proteolytic and lipolytic action of certain moulds, one of the most active being *Aspergillus fumigatus* A filtered culture of this mould to which tubercle bacilli had been added was incubated at 38 C for one month it was then found that one fourth of the bacilli had disappeared and that the remainder had lost their tuberculin acid resistance, and their virulence was attenuated Rabbits and guinea pigs injected intrameningeally with massive doses of the "macerated bacilli resisted subsequent intrameningeal injections of virulent tubercle bacilli Moreover guinea pigs injected subcutaneously with five drops of bacillary emulsion (in four doses at monthly intervals) survived for five to twelve months even when treatment was only commenced a month after infection The filtered fluid in weekly doses of 1 c c m was also active in guinea pigs Infected animals with cutaneous ulcers recovered and lived sometimes for more than a year Vaudremer has treated 15 cases of advanced surgical tuberculosis at La Salpetriere with a bacillary emulsion

prepared from four strains of virulent human tubercle bacilli and one strain of bovine bacilli grown for one month on glycerin broth, then macerated for another month in sealed flasks with a filtered culture of *Aspergillus fumigatus* The bacilli were then decanted, pounded in a sterile mortar, shaken up in distilled water, replaced in an ampoule, and boiled for five minutes These dead bacilli, contrary to the usual experience, were tolerated remarkably well by animals and man The emulsions are weak—scarcely opalescent, the dose is 0 5 to 1 c cm subcutaneously The cases were watched by the surgical staff of the hospital, most patients had pulmonary lesions in addition to their surgical tuberculosis, and yet rapid and complete cures are reported in every case Vaudremer concludes that it is possible to control the progress of surgical tuberculosis by subcutaneous injections of tubercle bacilli almost deprived of acid resistance, tuberculin free, and killed by boiling He did not detect any deviation of complement

399 Retrosplenic Abscess in Typhoid Fever

J SABRAZÈS, R DE GRAILLY, and DUCASSE (*Gaz hebd des Sci med de Bordeaux*, August 10th, 1924, p 498) state that collections of pus in the abdominal cellulo adipose tissue are rarely found nowadays in autopsies in cases of typhoid fever, but are probably more frequent than is supposed, as several cases were recorded by the earlier writers Three cases of perisplenic suppuration which was not discovered until the autopsy were reported in the pre bacteriological era by Griesinger The present authors record the case of a girl, aged 20, who had an attack of fever in which the pulmonary sym[illegible] After death, in addition to the intestinal lesions characteristic of typhoid fever and splenopneumonia of the left lung, an abscess was found in the retrosplenic region independent of the spleen, of the size of a pigeon's egg, without any perforation of the splenic capsule, inflammation of the mesenteric glands, or focus of osteitis or myositis The pus contained a pure culture of typhoid bacilli

400 Thrombosis of the Lateral Sinus

BINET of Besançon (*Rev de Laryngol, Otol et Rhinol*, August 31st, 1924, p 533) describes four cases of lateral sinus thrombosis following old standing middle ear suppuration All the patients were young, and three of the four were males The first patient had undergone several previous operations in the hope of eradicating the suppuration, and, permission for a further operation being withheld, ob eration continued until death For three and a half months the patient was under treatment for widely fluctuating temperature, frequent rigors, and attacks of hyperpyrexia There was a very profuse discharge from the ear, and an abscess formed around the jugular vein and had to be opened Finally, after a violent attack of headache, the patient passed into a state of coma and died Of the remaining cases, which were all operated upon, two recovered rapidly and the third died of pneumonia Binet points out that in very many cases the development of the thrombosis is very insidious, especially in the case of a mural clot and where the infection is very slight In some of these cases the first symptoms may be due to emboli The author points out the danger of curetting the sinus, and restricts himself to wide incision He believes in ligature of the jugular vein in addition to opening the sinus in all cases where the signs are well marked, and especially when there are rigors To stop the haemorrhage from the upper end of the sinus he adopts the plan of packing the interior of the sinus He remarks on the extreme rarity of gangrene of the inner wall of the dural coat of the sinus The only possibly successful method of treating the condition is that of immediate and most thorough operation

Therapeutics.

401 Intracardial Injection of Adrenaline

E A KOCH (*Zentralbl f Gynak*, October 11th, 1924, p 2234) reports the case of a child apparently dead from asphyxia neonatorum who was revived by an intracardial injection of adrenaline At birth the child made a slight movement, passed urine, and then lay still, deeply asphyxiated The cord was pulseless, so it was immediately cut, and mucus was aspirated from the trachea No heart beats could be heard, and heart massage and artificial respiration were resorted to without success After five or six minutes 6 minims of suprarenin were injected into the heart through an intercostal space, half an inch to the left of the sternum Almost immediately the heart started to beat, at first irregularly with numerous extra systoles—an occurrence previously noted by Frenzel All methods were tried to start respiration, but it was not until half an hour had elapsed that the child was made to breathe and the skin took on a more healthy colour No further trouble was experienced, and the child was well enough to suck from the breast on the second day Koch states that the injection must be made within fifteen minutes at latest after the heart has ceased beating, and that not more than 8 minims should be injected into an infant, as 12 minims has been known to cause convulsions in a six months old child He then examines recent statistics relating to the intracardial injection of adrenaline in other contingencies He maintains that it is of very great value in surgical operations when the heart failure is due to the anaesthesia, or in cardiac failure caused by internal bleeding, or in shock and collapse following spinal anaesthesia In such cases in adults a dose of 16 minims is injected, the number of reported successes is very striking, the statistics being taken from a number of writers Adrenaline is apparently of little use when the heart failure is due to internal derangements such as heart disease, and very few successes in such cases have been recorded

402 Fluid in Medical Treatment

S ISAAC (*Klin Woch*, October 21st, 1924, p 1962) discusses the restriction and increase of fluids in the treatment of various diseases The average amount of water required daily by an adult is, roughly, 3½ pints, one half to two thirds of this being taken as beverages, the rest as water in the food In cardiac diseases with dropsy, and in cases of high blood pressure, especially those associated with nocturnal dyspnoea, restriction of the fluids taken is of service In acute nephritis, and in some kinds of chronic nephritis, fluid restriction is also useful In granular kidney, when the renal functions are only slightly affected, circulatory disturbances and dyspnoea may be prominent symptoms, and in such cases fluid restriction relieves the circulatory disturbances and high blood pressure On the other hand, when uraemia threatens, abundance of fluid is necessary. In chronic nephritis, when dropsy is due to cardiac failure, as is frequently the case in granular [illegible] is occasionally of service, but otherwi[illegible] nephritis) restriction of sodium chloride in the diet is of more importance Restriction of fluid is useful in primary polydipsia, and in diabetes insipidus, combined with a suitable diet Increase in the fluids taken prevents retention of metabolic products in certain cases of granular kidney, and the large quantities of fluid drunk in various spa treatments aid the excretion of uric acid in gout Of greater importance is the abundant [illegible] haemorrhage, when fluids cannot be tak[illegible] elimination of toxins is necessary Fluids may be introduced by the rectum, subcutaneously, or intravenously The simplest form of administration is the drop enema—especially suitable when a continuous supply is desired For rapid introduction of fluid intravenous injections are mostly used, normal saline and other fluids being employed, but the author prefers a 5 4 per cent isotonic solution of grape sugar

403 Vaccine Treatment of Rheumatism

R LAUTIER (*Bull Soc de Ther*, October 8th, 1924, p 249) states that vaccine therapy in rheumatism was first carried out by Rosenthal (1909–10) with a vaccine obtained from strains of Achalme's bacillus isolated from patients with rheumatism and containing 5 million bacilli per cubic centimetre Rosenthal employed the vaccine in addition to treatment by a serum obtained from immunization of horses by injection of cultures of Achalme's bacillus Serum treatment was reserved for the acute attack, and the vaccine was injected in the intervals between the attacks, with the object of preventing relapses or cardiac complications Bertrand of Antwerp next tried a Wright's vaccine, also isolated from strains of Achalme's bacillus but his method differed from Rosenthal's in the number of bacilli in each cubic centimetre of the vaccine and its mode of application The vaccine was used during the attacks as well as in chronic rheumatism The first dose consisted of 25 million bacilli and each subsequent dose was increased by 25 million, the second being given twenty four hours after the first in acute cases and forty eight hours after the first in chronic cases Lautier, who has employed Bertrand's method for the last two years, has found that it is superior to the ordinary treatment for rheumatism, and has never had any bad results from its use An acute attack was usually cut short before more than 150 million bacilli had been given, while in chronic forms it was sometimes necessary to give larger doses, such as 250,375 million bacilli or more The treatment should be continued even after clinical recovery, so as to prevent relapses After the treatment has been completed one to four injections a year of a dose of 25 million bacilli are sufficient, especially in chronic rheumatism.

Diseases of Children.

404 Prognosis of Tuberculosis in the First Year of Life

C VAN DAM STOKKINK (*Nederl Tydschr v Geneesk*, September 13th, 1924, p 1348), after a review of the literature, according to which the mortality from tuberculosis in the first year of life ranges from 67 to 85 per cent, states that he has collected 144 cases of tuberculosis in children of this age treated at the Emma Children's Hospital in Amsterdam In most of the cases the diagnosis was established by bacteriological and clinical examination but in some instances it was not made until the autopsy The youngest child was only 18 days old No evidence of tuberculosis was found in this case on clinical examination, but *post mortem* a tuberculous focus was found in the lung The mortality among the 144 cases was 76 per cent The youngest of the 35 survivors was 2 years, and the oldest 15½ years The prognosis during the first six months was very unfavourable as out of 40 children 35 died—a mortality of 90 per cent, while in the second half year the mortality was 66 per cent Of the 144 patients 95, or 87 per cent, died in the first year, 9 per cent in the second, and 3 per cent in the third year No fatalities occurred after that period Sex had no influence on the mortality, as among 133 children, of whom the sex was stated, the mortality was the same (73 per cent) among 68 males and 65 females The mortality was decidedly higher among the artificially fed than among breast fed children, as is shown by the following figures Among 43 children breast fed longer than three months the mortality was 77 per cent, and among 29 children breast fed only a short time 76 per cent, while among 24 children artificially fed it was 92 per cent The source of infection was discovered in 81 cases in 27 it was the father, in 28 the mother, in 3 both parents, in 12 a brother or sister, in 4 the grandfather or grandmother, and in 7 neighbouring families According to Ehasberg, tuberculosis in the children of tuberculous families does not run such an unfavourable course as in children with a non tuberculous environment In the former the mortality is less, and in the fatal cases the disease has a longer course Dam Stol kink's experience was similar, as he found that the mortality of children of tuberculous families was 74 cent, as compared with a mortality of 81 per cent among children of non tuberculous families

405 Vulvo vaginitis in Children

E APERT (*Journ de Med et de Chir Prat*, September 10th, 1924 p 609) states that simple vulvo vaginitis complicating measles, whooping cough, febrile catarrh, or other acute febrile disorders of children yields readily to copious irrigation with warm normal saline solution which has been made slightly alkaline When there is no such concomitant disease the presence in a child of a thick yellowish green discharge which leaves a thick stain on the linen points to gonococcal vulvo vaginitis, and the diagnosis is easily made by microscopical examination In treatment local measures are of paramount importance, although exhibition of arsenic, lime, and iodine is useful The child is placed flat on a couch with the hips flexed and abducted, and the external genitals are sponged with a 1 in 4 000 solution of potassium permanganate, the vagina being gently irrigated with the same solution through a soft india rubber catheter (number 8 or 10) The container should not be placed more than 4½ inches above the vaginal orifice, since injections at higher pressure are liable to convey infection to the supravaginal regions of the genital tract Urethral infection is rare in children, but if pus can be squeezed from the urethra a few drops of 2 per cent protargol should be injected into it During the first few days of treatment the patient should be kept in bed Gonococcal peritonitis is a rare complication it occurs with great acuteness but clears up without necessitating surgical intervention Gonorrhoeal arthritis is much less common than in the adult, sensitized vaccines have a place in treatment and antigonococcic serum, if used, should be injected into the affected joint

406 Causes and Treatment of Otitis Media.

OUT of 613 children admitted to an American hospital from February to August, 1923 no fewer than 33 4 per cent had otitis media or developed it subsequently The children came from poor homes and had been artificially fed The incidence of the otitis varied with the season of the year (as in acute respiratory diseases) with the type of associated disease (pneumonia, dysentery, nasal diphtheria pertussis and pyelitis) and with the age the susceptible period being 3 to 15 months D T SMITH (*Amer Journ Dis of Children*, July, 1924, p 1) considers therefore, that there is probably an associated vitamin deficiency since the age period and the seasonal variation correspond with those of rickets and scurvy and the children had been artificially fed Eighteen of the thirty cases of rickets had otitis media rats deprived of fat soluble vitamin A developed otitis media (Daniels, Armstrong and Hulton, 1913) The causal organism was a haemolytic streptococcus in 50 per cent of cases, other streptococci and staphylococci were frequent, while the pneumococcus even in otitis associated with pneumonia, was surprisingly infrequent Otitis may be contagious and epidemics have been recorded Smith then gives details of a new and satisfactory method of treatment He points out the vital importance of clearing the pus from the external auditory meatus and introducing the antiseptic into the middle ear A long clean incision is made into the posterior inferior quadrant of the tympanic membrane The ear is then irrigated with half strength peroxide solution by means of a medicine dropper with a rubber bulb Peroxide solution is chosen because it liquefies the pus and indicates the presence of more pus by frothing The external ear is swabbed dry and an antiseptic dropped in from a clean dropper and washed to and fro Ten to fifteen drops of a 0 5 per cent solution of sodium hydroxy mercury benzo phenone sulphonate, freshly made from tablets and repeated three or more times in the twenty four hours according to the severity of the case, cleared up infections of the colon bacillus rapidly and improved streptococcal infections The addition of 2 per cent of acetic acid to the solution was found to make it effective for *B pyocyaneus* Gram positive organisms were treated by giving alternate irrigations with gentian violet solution (up to 5 per cent) By this method 80 cases of acute and chronic otitis media were cured in less than a fortnight from the onset No case of mastoiditis followed the treatment

Obstetrics and Gynaecology.

407 Medical Treatment of Salpingitis

ACCORDING to A SIREDAY and P BROCQ (*Journ de Med et de Chir Prat*, September 10th, 1924, p 621), it is almost universally agreed that in cases uncomplicated by tubal rupture or torsion of an ovarian cyst, acute salpingitis—with severe pain, peritoneal reaction, and vomiting or nausea—yields to medical treatment Complete rest in bed in a horizontal position is essential The application to the hypogastrium of ice bags may with advantage be associated with very gentle abdominal massage with a paste of collargol 77 grains lanoline 3 drachms and vaseline 4½ drachms each morning and evening The ice bags should be renewed every three hours The authors find that morphine is usually required, but administration of antipyretics is without value and may be harmful The copious and hot vaginal douches which were formerly given in many cases are injurious for they interfere with the patient's repose, but gentle irrigations of 4 ounces of boiled water, at a temperature of 102 to 104 F, to which 25 drops of tincture of iodine have been added, may be made At this stage cathartics are contraindicated The treatment of subacute salpingitis—whether subacute from the beginning or the sequel of an acute stage—is similar save that hypodermic administration of morphine may be replaced by rectal injections of 4 ounces of water containing 15 grains of antipyrin and 20 to 30 drops of laudanum Helio therapy is a valuable adjunct to treatment in the subacute stage the first exposures should not last longer than ten minutes In chronic salpingitis vaccine therapy and thermal cures play a useful part In certain cases also benefit is gained from packing the vagina with a long band of gauze of which the upper end is impregnated with one part of ichthyol in ten of glycerin

408 Hydatidiform Mole.

J A VAN DONGEN (*Nederl Tydschr v Geneesk*, October 11th, 1924, p 1824) in the course of seven years has seen 16 cases of hydatidiform mole among 4 000 cases of pregnancy so that hydatidiform mole occurred once in every 250 pregnancies This figure agrees with that given by Kroemer who found 15 moles among 3 856 pregnancies A Mayer reported one case among 310 deliveries, Seitz estimated that one case of mole occurred in every 500 pregnancies while Treub's estimate was 1 in 1,000 and van der Hoeven's 1 in 2 000 According to most writers hydatidiform mole is more frequent in older women than at an earlier period of life Frey, Walther and Stoppel have recorded cases at 51 53 and 54 respectively Gies, who reported 30 cases found that hydatidiform mole was seven times as common in pregnant women over 40 as below that age Seitz maintains that about 25 per cent of the cases occurred between 40 and 50 and Walther declares that 16 5 per cent of his cases were between 40 and 50 and 2 8 per cent were still older On the other hand, none of van Dongen's patients were elderly women Only one, aged 42, was over 40 and only four

between 30 and 40 The youngest was aged 16, and there were six aged 18, 19, 20, 20, 21, and 22 respectively Several writers have stated that hydatidiform mole is more frequent among multiparae than among primiparae In van Dongen's series there were three primiparae and thirteen multiparae The mole is usually expelled between the second and seventh month of pregnancy Among van Dongen's patients pregnancy had lasted two months in one, two and a half months in two, three months in three, five months in three, four months in one, four and a half months in one, five months in three, five and a half months in one, and six months in one when the mole was expelled In all the cases expulsion of the mole was preceded by more or less severe haemorrhage, in most cases for a long period, so that most of the patients were rather anaemic In six cases, or 37 5 per cent, hyperemesis occurred Albuminuria was present in seven cases, or 43 75 per cent, in two there was only a trace of albumin, in four it was somewhat greater, and in one it was 8 per 1,000 In six cases ovarian cysts were present, the size of the cysts ranging from that of a small hen's egg to that of a large orange Only one patient died, and she was moribund from haemorrhage when admitted to hospital In none of van Dongen's cases was the mole spontaneously expelled, but the uterus had to be emptied with a polypus forceps and curette, with or without previous dilatation of the cervix

409 Childbirth and Venereal Disease

ACCORDING to E A SCHUMANN (*Amer Journ Obstet and Gynecol*, September, 1924, p 257) the frequency of gonorrhoea as a complication of pregnancy has been exaggerated in a series of 150 private patients in whom routine bacteriological examination of a cervical smear was done the gonococcus was detected once only For this reason, and also because it has been shown that the Fallopian tube is rarely a focus of chronic gonorrhoeal infection, he thinks it is probable that the gonococcus has little importance as an active agent in the production of puerperal sepsis Extension of a gonorrhoeal cervicitis or urethritis to the endometrium and tubes during pregnancy is a common event that the extension has occurred in pregnancy is proved by the finding that the tubes are occluded, and probably many cases of one child sterility may find their explanation thus Schumann recommends that if vulvalor cervical gonorrhoeal infection is manifested during gestation, treatment should be directed to localizing the disease, while avoiding any traumatism which might lead to its extension The entire vagina and cervix should be gently coated with 20 per cent argyrol solution at weekly intervals, while the patient should instil 2 to 4 oz of a 10 per cent solution into the vagina each day The profuse irritating leucorrhoea which sometimes occurs responds to the free use of a powder containing equal parts of sodium bicarbonate and fuller's earth retained for forty eight hours on a cotton tampon With regard to syphilis the author infers from his own records that pregnancy in an untreated patient may be expected to lead to the birth of a living healthy infant in about one half of the cases This proportion is probably increased to over 70 per cent if the patient is subjected to intensive treatment during gestation If adequate treatment is given, the chances in subsequent pregnancies of the birth of a healthy infant are but little less than in non syphilitic subjects.

Pathology.

410. The Wassermann Reaction in Leprosy.

R B LLOYD, E MUIR, and R G C MITRA (*Indian Journ. Med Research*, July, 1924, p 213) have examined the effects on the Wassermann reaction of treating leprosy cases with antisyphilitic remedies, with a view to determining the part played by coexisting syphilis in producing positive reactions The percentage of positive reactions was lowest in the anaesthetic type of leprosy (27 per cent), and in twelve out of sixteen positive cases the reaction was favourably influenced by treatment The authors believe that the explanation of the lower incidence of the positive Wassermann reaction in nerve cases is to be found in the fact that the leprosy bacilli in the nerves are few in number, and but little production of antibodies is to be expected They advise, therefore, that in all cases of nerve leprosy the Wassermann test should be performed before treatment is commenced, since if the reaction is negative, as it will be in 75 per cent of the cases, no antisyphilitic treatment will be required If the reaction is positive, however, and particularly if there are indications that the case has been of the primary nerve type from the first, they recommend a course of antisyphilitic treatment, even in the absence of a specific history, antileprotic treatment being commenced subsequently In skin cases the authors find that a positive reaction was favourably influenced by antisyphilitic treatment in more than half the cases, and in about one third of them it became negative They conclude that coincident syphilitic infection, though possibly not the only cause of the Wassermann reaction, is a potent factor in both types of leprosy In a former paper (*Indian Journ Med Research*, July, 1923) the authors had described their study of two series of children of leper parents, living under similar conditions in the same place, totalling 104 individuals, of these, 58 became infected with leprosy, 62 per cent presenting positive Wassermann reactions The remaining 46 children did not develop leprosy and their Wassermann positive rate was only 17 per cent The authors express the opinion that the high proportion of positive reactions in these leper children cannot be attributed to syphilis.

411. The Diagnostic Value of Lumbar Puncture in Late Syphilis

J LOFTHUS (*Norsk Mag f Laegevidenskaben*, September, 1924, p 705) has compared the Wassermann examination of the serum and cerebro spinal fluid with the numerous other tests, including cell counting, of the cerebro spinal fluid in several cases of late syphilitic lesions, such as general paralysis and tabes Among the tests of the cerebro-spinal fluid were those associated with the names of Nonne, Apelt, Pandy, Weichbrodt, and others In some cases the cerebro spinal fluid gave a negative Wassermann reaction, although the other reactions were positive Thus, of 90 patients suffering from general paralysis, only 73 gave a positive Wassermann reaction in the cerebro spinal fluid The serums of 70 patients suffering from general paralysis gave a definitely positive Wassermann reaction in 49 cases only, yet there could be no doubt as to the correctness of the diagnosis founded on the clinical evidence and the examination of the cerebro spinal fluid by cell counting and other tests The author concludes from his observations that it is unjustifiable to discard the diagnosis of general paralysis simply because the Wassermann reaction is negative both in the cerebro spinal fluid and in the serum A diagnosis of general paralysis founded on a careful clinical examination and the demonstration of morbid reactions in the cerebro spinal fluid, other than the Wassermann reaction, is perfectly justifiable whatever the nature of the Wassermann reaction

412 Basal Metabolism of Fat

E O FOLKMAR (*Ugeskr f for Laeger*, October 9th, 1924, p 762) has investigated the basal metabolism of 21 women, 10 of whom were suffering from adiposity alone, while the remainder were suffering also from well defined adiposalgia In no case was there evidence of advanced cardiac insufficiency or of catarrh of the respiratory tract In every case the basal metabolism was found to be reduced, the reduction varying from 3 to 20 per cent These findings doubtless represented an underestimate of the reduction of the basal metabolism, for the conditions under which the investigations were carried out were not ideal, the patients' pulses often being faster than usual at the time of the examination No relationship was established between the degree of reduction of the basal metabolism and the age and weight of the patients With regard to treatment in these cases, the author has controlled the influence of various thyroid preparations by means of concurrent basal metabolism examinations, and, with the exception of only one preparation, which was Danish, he found that the various thyroid preparations on the market were either inert or very variable in their action Only on one occasion did he have to discontinue thyroid medication for a short time on account of the palpitation of the heart provoked Generally speaking, he regards the processes leading to adiposity as representing a vicious circle requiring intervention by such means as reducing the dietary and carefully training the patient's muscles to enable her to take more exercise

413 The Spleen in Diseases of the Blood

W J MAYO (*Journ Amer Med Assoc*, September 13th, 1924, p 815) discusses certain blood conditions depending on pathological processes in the spleen, and concludes that in the light of clinical experience a chronically enlarged spleen must be regarded as a menace to the well being of its human carrier, and that it rests with the physician to show why it should not be removed He refers to 255 cases of splenectomy performed in the Mayo clinic for splenic anaemia, haemolytic icterus, pernicious anaemia, splenomedullary leukaemia, polycythaemia, and purpura In all these diseases Mayo discusses the relationship of the spleen to the blood condition, and lays emphasis on its connexion with pathological changes in the white cells

The ENERGEN STARCH-REDUCED BREADS and PRODUCTS

supply all the requirements of dietetic treatment with cereal foods

ENERGEN GLUTEN BREAD

This is plain Energen Bread specially prepared for DIABETES, standardized to to contain definite percentages of **protein and carbohydrate,** thereby admitting of their exact dosage in the diabetic patient's dietary

Energen Bread is strongly indicated in all forms of INDIGESTION As it contains three to four times as much gluten (protein) as ordinary bread, very small quantities suffice for nutrition When Energen Bread is given, the volume of food is greatly decreased, and **functional rest is thereby secured** Energen Bread is made without yeast, baking powder, or other admixture, and does not give rise to stomachic reactions, and the possibility of intestinal fermentation is reduced to a minimum by the elimination of a high proportion of the starch

This combination of qualities has made it possible to give **Energen Bread** in many severe cases of gastric and intestinal affections in which **no other form of cereal food was tolerated**

ENERGEN WHEATMEAL BREAD

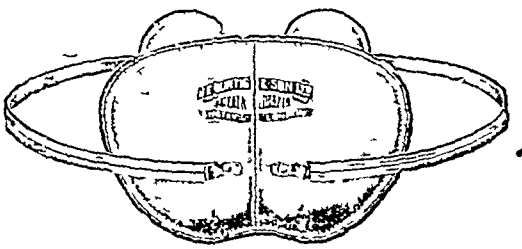
contains a considerable amount of the natural "roughage of the wheat berry incorporated with the gluten Useful for all cases complicated by INTESTINAL STASIS, or for patients who prefer brown bread The proportions of **protein** and **carbohydrate** are the same as those of the ordinary Energen Batons

ENERGEN CASEIN BREAD

contains an increased percentage of protein (gluten and casein), of high biological value Specially indicated in all cases of DEBILITY arising from malnutrition, and during convalescence and post operative periods It is also a most sustaining substitute for ordinary bread in dietaries for acute RHEUMATISM, etc, from which meat is excluded

ENERGEN MIGNONETTE ROLLS

This is a special form of the Gluten Bread for use in OBESITY, ensuring a heavy reduction of the proportion of carbohydrate food, which is the outstanding feature of dietetic treatment



The Energen Dietetic Products (Flour, Macaroni, Semolina, etc) may be associated with the above in all cases in which a diminution of carbohydrate and an increase of protein are desired

N B —Samples of Energen Bread and Preparations with Analyses and full particulars sent to all practitioners on demand

The Natural Mineral Waters of

CARLSBAD

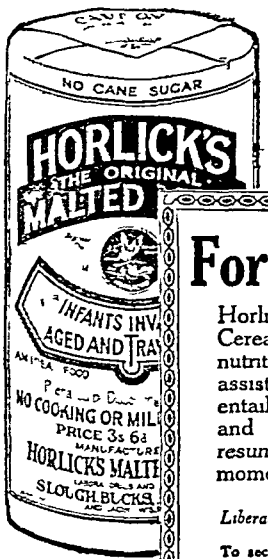
SPRUDEL, MUHLBRUNNEN & SCHLOSSBRUNNEN.

These Waters act

(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pain and spasms in these organs, and stimulating the digestive organs into activity

(2) Through the blood That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, &c.)

Largely Prescribed in cases of



Chronic Gastric Catarrh, Hyperæmia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen and of the Kidney and Urinary Organs

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents—

INGRAM & ROYLE, LTD.,

Bangor Wharf, LONDON, S E 1. And at LIVERPOOL and BRISTOL

Catarrhal Conditions

of the Respiratory Tract

THERE is abundant clinical evidence to show that a bacterial vaccine properly prepared, and intelligently used, will go a long way towards controlling troublesome catarrhal infections

Results following the use of Mixed Vaccine for Colds and other Respiratory Catarrhs have been eminently satisfactory Perhaps no other measure has been so successful in cutting short a "cold" as the prompt injection of this vaccine, in initial doses of 0 1 c c in an acute case and 0 2 c c in sub acute conditions, combined with therapeutic treatment for the reduction of congestion.

For prophylaxis, three graduated doses of Anti-Catarrh Vaccine are recommended at intervals of seven days

A booklet, 'Vaccine Therapy' containing full particulars will be sent post free on request by

PARKE, DAVIS & CO., LONDON, W.1.

A VALUABLE FOOD BISCUIT

MACFARLANE LANG & CO.'S
DINNER TOAST

The DINNER TOAST biscuit, the latest addition to our series of Food Biscuits, is composed of the finest wheaten flour, pure butter malt and milk, contains but a trifling percentage of moisture, and makes a crisp, crusty appeal to the palate

Primarily it has been introduced for persons of dyspeptic tendencies who cannot partake of ordinary bread or toast with comfort For such, the DINNER TOAST BISCUIT both from the standpoint of EASE OF DIGESTION AND HIGH CALORIC VALUE, provides an excellent substitute

Taken also with a glass of milk, a cup of beef tea or other nutritive fluid, the DINNER TOAST biscuit makes a sustaining emergency meal

Send a postcard for Sample to

is now ready, 27/6 net, post free 28/-

NEW CHEMICALS, DRUGS, AND METHODS OF TREATMENT.

The following are a few brief notes to give a mere outline of the additions

ALKALOIDAL NOTES This chapter contains some very interesting observations regarding "Activated" Alkaloids, and in addition, the description of a series of Alkaloidal Periodides The preparations may, in both cases, be useful additions to the physician's armamentarium

ASPIRIN COMPOUNDS, include therapeutic notes upon the various new halogen derivatives

BISMUTH, ORGANIC COMPOUNDS The "pros and cons" of these competitors to Mercurials, and their chemistry are described in six pages

COLLOIDAL METALS The chapter contains, as new, Colloidal Calcium, Colloidal Lead, also notes upon the Colloidal Gold treatment of neurasthenia, alcoholism, and the morphine habit

EMETINE and COMPOUNDS Fifteen pages on new bodies in dysentery

ACCESSORY FOOD FACTORS, with practical hints for making preparations to retain the factors unimpaired.

CHAULMOOGRA PREPARATIONS New compounds in the treatment of leprosy, tuberculosis, etc

INSULIN, eight pages devoted to technique and clinical experience

QUINDINE and CINCHONIDINE bodies in heart affections

NON-IONISABLE MERCURIALS VACCINES ORGANOTHERAPHY INTRAVENOUS TREATMENT DANGEROUS DRUGS ACTS INSTRUCTIONS

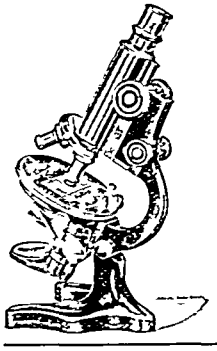
THE
New Jaeger Underwear

A Consulting Physician writes —

"In my opinion this invention of a Two layer Stockinet weave constitutes a distinct advance The layers are so ingeniously woven that for all practical purposes the material behaves as a single fabric whil t the air contained within the meshes acts as a bad conductor of heat renders the garments more hygienic and at the same time lighter in weight than their somewhat bulky winter weight predecessors



In wear the fabric is warm and comfortable and the texture is fine enough not to be irritating

Intestinal Disinfection

No 11.

MUCOUS AND OTHER FORMS OF COLITIS

Conditions of Colitis occur at all ages and lead to much suffering, ill-health and chronic invalidism They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present KEROL is the one substance which possesses this power and its administration has cured many a case of mucous colitis

For intestinal disinfection use KEROL CAPSULES (keratin-coated), they contain 3 minims of Kerol One to three Capsules may be given three or four times a day after meals

KEROL CAPSULES

Please send for literature and samples which will be sent free to any member of the Medical Profession

Total Premiums	£38,032	£41,582
LIFE FUND		
New Assurances (net)	£77,950	£137,360
New Annual Premiums (net)	£2,901	£4,446
Total Premiums	£8,461	£12,386
Total Premium Income of the Society	£47,043	£53,969
Total Funds	£368,241	£391,916

The special feature of the Society's Sickness and Accident Contracts is that they are non-terminable by the Society, except in the event of a breach of the conditions by the assured, thus securing a permanent income in the event of a prolonged illness

The Society's special Combined Policies, under which Sickness and Accident Insurances, and Endowment Life Assurance can be obtained in a single Policy at less cost than by taking out two separate Policies, are becoming increasingly popular amongst members of the medical profession

These Policies entitle the holder to share in the surplus profits, both of the Sickness Fund and of the Life Fund, and are, therefore, a remarkably good form of investment

THE MEDICAL SICKNESS, ANNUITY & LIFE ASSURANCE SOCIETY, Ltd.

300, HIGH HOLBORN, LONDON, W.C.1.

GAS FIRE ADVANTAGES

The gas fire is instantly available day or night
It burns silently and without attention, and consumes fuel only as long as heat is required
Its heat can be instantly varied by a turn of the tap, so that an equable temperature is easily maintained in any room
It is ashless and smokeless, and so promotes health, saves considerable household work, simplifies the Servant Problem and helps to abolish the Smoke Nuisance
The modern gas fire heats by radiation—Nature's ideal method of warming—and therefore does not dry the air of a room, but, correctly fitted with an adequate flue, keeps it constantly ventilated
On these grounds the gas fire has won the widespread approval of the medical profession

The B C G A
representing the British Gas Industry, is at the service of the public, without charge, for advice and help on any subject, large or small, connected with the economical and efficient use of gas in home, office, or factory
A letter to the Secretary of this Association will receive prompt and careful attention

ADVANCE IN TREATMENT
of
Hyperchlorhydria and Associated Conditions

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory They may give momentary relief to the painful condition but they also have the effect of aggravating the morbid condition. For this reason they are distinctly contra indicated especially in stubborn cases

Alocol does not neutralize acid it absorbs the excess colloido chemically and at the same time leaves a sufficiency for normal gastric digestion The outstanding advantage of Alocol as an antacid is that it removes from the stomach the excess of the acid radicle (Cl) instead of merely temporarily neutralizing it Alocol can be used for prolonged periods without the slightest harmful effect

A supply for clinical trial with full descriptive literature sent free on request.

M. 137

Alocol is indicated in all conditions in which diagnosis reveals high gastric acidity It is particularly valuable in the treatment of chronic affections of the stomach the dyspepsias especially those of pregnancy gastric and duodenal ulcer gastrosuccorrhea and in conditions characterized by gastralgia, pyrosis, flatulence acid eructation and other symptoms common to gastric disease.

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop Quite a series of acids are then to be met with (butyric, lactic, acetic, etc), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and thus avoids stagnation and consequent fermentation As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition

CAUTION —Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ÉTAT" and the name of the SOLE AGENTS —

Cod-liver Oil

In a new Form A Deliciously Flavoured Jelly Free from all Taste and Odour of Cod-liver Oil

In all conditions where Cod-liver Oil is required, and where it cannot be taken owing to its repellent fishy flavour and odour, "Gadus" Jelly is strongly recommended

This delicious preparation has been perfected after much experiment by the noted Norwegian Chemist, Peter Moller Heyerdahl "Gadus" Cod-liver Oil enjoys a high reputation in Norway and Sweden,

and attracted considerable attention when exhibited at the British Medical Exhibition of 1920

The valuable nutritive principles of "Gadus" Jelly are not in the least destroyed in the process of manufacture, and it is approximately 100 times richer in Vitamins than butter

"Gadus" Jelly is an extremely palatable product and is readily taken by children and invalids

HEYERDAHL PRODUCTS CO. (England) LTD.,
36, Regent Street, Cambridge.

The normal functioning of Lymphoid Tissue

Marmite an Invaluable Agent

IT has now been established that the absence of B Vitamin from the diet causes atrophy of the lymphoid tissue, including the spleen, thymus gland and Peyer's patches, and a diminution of the small lymphocytes in the blood (*Lancet*, Dec 10th, 1921, pp 1202-1209 and 1228, and *Lancet*, March 29th, 1924, p 633)

If the dietary error is not corrected, loss of appetite, intestinal stasis, malnutrition, marasmus and ultimately death result The restoration of B Vitamin to the diet in the form of Marmite, a food especially rich in B Vitamin, readily removes the untoward symptoms and danger

Marmite is a preparation of Yeast It is so extremely palatable that it forms an appetising addition to soups, stews and all meat dishes It also makes an excellent sandwich Medical men will therefore find Marmite a readily acceptable food for patients suffering from conditions which indicate a need for increased supplies of B Vitamin

Marmite

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness

THE MARMITE FOOD EXTRACT CO, LTD, 59, EASTCHEAP, LONDON, EC3

A welcome addition to Convalescent Diet

So many Medical Men have found in "Skippers" an item of considerable dietetic value in cases where the patient needs sustaining fatty food, but lacks the appetite for the more usual forms of it

Skippers are tiny silvery fish of delicate flavour They are free from the hard bones and scales so often found in other fish, because they are quite different and packed under hygienic conditions, by an improved process

Skippers are Norwegian Brisling caught in the clear cold northern waters and packed in the purest olive oil They are most digestible and provide just those phosphates and fats that are particularly useful for "feeding up" children and invalids whose appetites are difficult to tempt

Few foods combine such nutriment with attractive flavour and digestibility

"Skippers"

FREE FROM HARD SCALES OR BONES

SKIPPERS in Oil or Tomato are guaranteed to contain no preservatives

ANGUS WATSON & CO LIMITED Ellison House NEWCASTLE-UPON TYNE

Phenomenal Success of DETOXICATED CORYZA VACCINE.

WITH so many coryza vaccines on the market, the unprecedented demand for our new *Detoxicated Coryza Vaccine* clearly indicates the physician's preference.

As a result of extensive researches, we have added to the main catarrhal organisms in our new detoxicated coryza vaccine, several newly-discovered germs. Thus a more complete all-round protection is assured

Moreover, our detoxication process has been reduced to an exact science by the introduction of special germ-disintegrating machines and the use of weak chemicals, which do not injure the *antigenic* properties of the germ Therefore large doses may be given with a correspondingly high degree of immunity

DOSAGE.—For Prophylaxis—an initial dose of 10,000 millions may be worked up, between intervals of seven days, to 50,000 millions For treatment—an initial dose of 5,000 millions may be worked up, between four and five day intervals, to 20,000 millions In chronic nasal catarrh or chronic bronchitis a prolonged treatment amounting to ten or twelve injections may be required, and the dosage should be gradually increased up to 100 000 millions

PRICES:

The new Detoxicated Coryza Vaccine is supplied as follows

		£	s	d
Phials, 1 c c, containing	5,000, 10,000 or 20,000 mils	-	3	0
„ 1 c c, „	50,000 mils	-	3	6

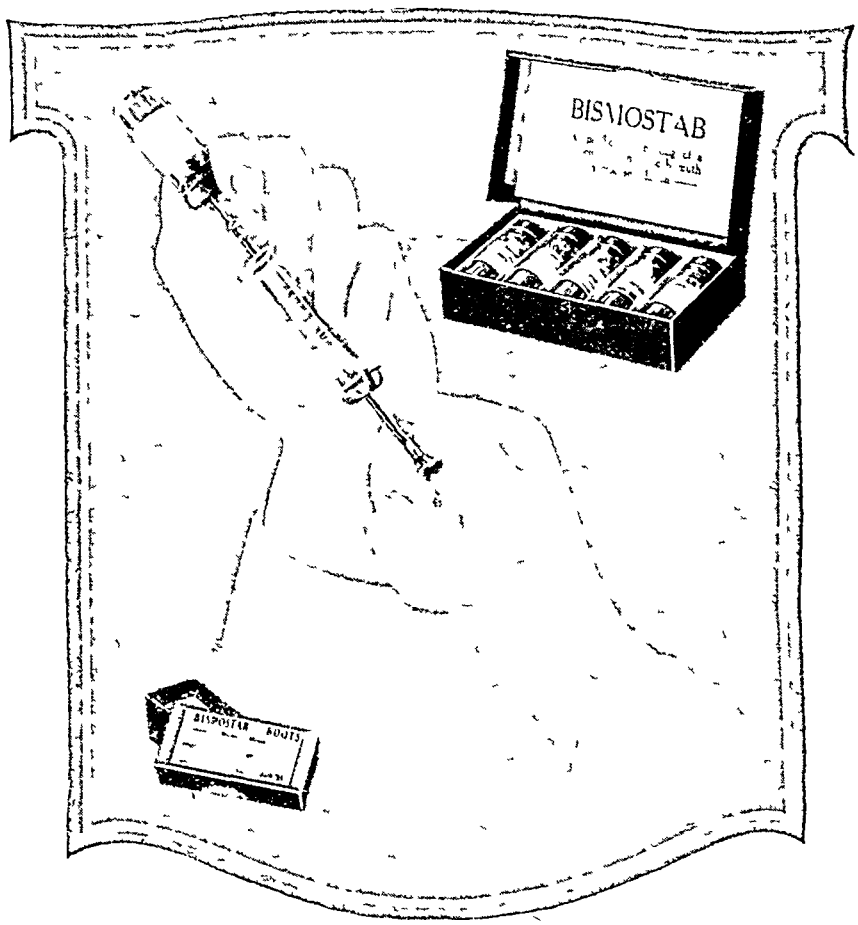
Buffer Value in the digestion of Infant Foods

Recently the importance of Buffer Value as an index of digestibility has become appreciated. A well-known physician, writing in the *Lancet* April 19 1924 showed that Almata alone among the infant foods he examined gave a buffer value approaching that of human milk. The significance of this is shown below



The diagram represents the amounts of Human Milk, Almata and Cows' Milk respectively which can be rendered digestible (brought to the optimum hydrogen-ion-concentration for gastric digestion in the human infant) by the same amount of hydrochloric acid of the gastric juice in each case

Not only Vitamins

BUT —

While Virol has been definitely proved to contain the vitamins, it does not, like so many foods, found its claim to the attention of the Medical and Nursing Professions merely upon its vitamin content The presence of vitamins is a minimum, not a maximum requirement

Correct Balance

In Virol the relative proportions of Protein, Fat, Carbohydrate and Mineral Salts are carefully adjusted, thus providing the ideal diet for growth For it has been shown that there is an interaction of the various food elements, and their effective influence on growth is dependent on their correct balance

Perfect Digestibility

Many concentrated foods are either tolerated with difficulty by the stomach or, when digested, throw an undue strain upon the organs In Virol neither of these defects is present, the fat is presented in the form of a highly digestible emulsion, and the proportion of protein is not so high as to give rise to derangement of nitrogenous metabolism

It is for these reasons that

VIROL

is used in over 3,000 Hospitals and Welfare Centres

IN JARS 1/3 2/ and 3 9 VIROL LTD 105 CEDAR ST PAUL C 1

Roboleine

completely solves the problem of supplying nourishment to delicate people of all ages, and to convalescents This statement is amply confirmed by the experience of the hundreds of doctors who have prescribed 'Roboleine' with success for many years It is significant also that 'Roboleine' should receive such praise as is contained in a letter from the Governor of the London Hospital, viz "The effect on some of our anæmic and rickety children has been magical"

FORMULA:

Marrow from the long bones, Red Marrow from the rib bones of prime oxen, 'Cream of Malt,' Egg Yolk, and Neutralized Lemon Juice

CONSTITUENTS

Animal Fats, Maltose, Diastase, and natural Nitrogenous and Phosphoric Compounds

The undoubted Clinical results obtained by 'Roboleine' are due to the fact that the body-building elements constitute nourishment without overburdening or clogging the system

THE EARLIEST HISTORICAL STONE RELICS OF CHINA.—The 'Stone Drums' three of which are here reproduced, are held in high veneration by the Chinese as having belonged to the Chou dynasty pioneers of Far Eastern civilisation and on account of the ancient instructions preserved upon them. They are very interesting and precious to the outside archæologist and philologist for unlike Egypt and Mesopotamia China yields no actual stone sculpture or inscriptions in stone with this one exception, down to the first century B C though such appear to have existed about 500 B C since references to carvings and sculptured bas reliefs occur in Chinese literature. The drums are ten in number and are in reality large water worn boulders roughly chiselled into drum like pillars 1' ft to 2ft. high and averaging 7ft in circumference Each is inscribed in early Chou characters with a separate ode but being much weathered only one remains nearly complete. The inscriptions provide us with a glimpse into the light-side of the lives of those who founded the empire for they celebrate an imperial hunting and fishing excursion and record how that the roads had been levelled and the water courses cleared for the great event by troops under the command of the feudal princes I appears likely from later similar records that the emperor thus marked his return from a successful military expedition. One of the odes opens thus

Our chariots were solid and strong
Our teams of well matched steeds
Our chariots were shining and bright
Our horses all lusty and slick

Note on the use of Dimol

in

SURGERY

IN view of the experience of a large number of observers who have found that the growth of gas-producing organisms which cause severe pain after abdominal operations may be effectively controlled by the use of Dimol, a distinguished surgeon has suggested that its free administration, both before and after the operation, would obviate the discomfort and pain which only too often follow such surgical measures.

As the experience of surgeons has proved that flatulence, if not controlled, may even imperil life, the above procedure should be worthy of serious consideration.

An Address
ON
WET WINDS AND EARLY PHTHISIS

DELIVERED TO THE SOUTH-WESTERN BRANCH OF THE BRITISH MEDICAL ASSOCIATION
BY
WILLIAM GORDON, M.D., F.R.C.P.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL
PRESIDENT OF THE BRANCH

THE subject which I have chosen for my address is one which I hope will be considered appropriate. It has been closely associated with the south west, for its initial observation was made in Devonshire, and its subsequent development owes much to the able and generous help of Devon colleagues. At the present moment fresh figures compel fresh insistence upon it. Its importance now spreads far beyond the limits of its native county. I have tried in every way in this investigation to avoid mistake, and, above all, to escape the pitfall of bias in my own mind. What is more difficult to eliminate is bias in the minds of others.

To convey to you the full significance of the tables I am going to place before you, illustrating the influence of rain-bearing winds on the fate of early cases of phthisis, it is necessary very briefly to review the work which has led up to them.

The Initial Observation

Twenty-five years ago, in the autumn of 1899, I compared the phthisis death-rates of the rural sanitary districts of Devon in the hope of discovering the best site for a phthisis sanatorium, and found, to my great astonishment, that the localities then accounted ideal, sheltered from north and east winds but open to the south and west, were precisely those in which the mortality from phthisis was highest. I tried to explain this distribution of the death-rate by reference to general sanitation to geology and to rainfall and failed. Nothing except exposure to west and south-west winds seemed to offer a satisfactory explanation. But this explanation was so contrary to the time-honoured teaching of the day that nothing but a searching test could have convinced me of its validity.

The First Test

This test was as follows. I chose four separate rural sanitary districts in different parts of the county, with an aggregate population of over 85,000 persons, and examined the phthisis death-rates in their parishes (the small areas of parishes allowing of fair comparison of relative shelter and exposure), and in every one of these districts the correspondence between relative exposure to west and south-west winds and relatively high phthisis mortality was found strikingly apparent. These figures were read to a meeting of the Royal Medical and Chirurgical Society in 1900.

The Second Test

After it had been urged (rightly) that *female* death-rates would furnish safer conclusions than mixed death-rates, and (wrongly) that wind from any quarter might be equally hurtful, I took for investigation Okehampton Rural District in the centre of Devon, presenting specially marked contrasts of exposure and shelter in respect of all winds except the south (which practically does not reach it), and constructed from it not merely tables but, to make the test severer, maps both of the female parish phthisis death-rates and of the relative parish exposures *in respect of south-west, west, north-west, north, north-east, east, and south-east winds*. In this undertaking I had the invaluable help of my friend Dr. J. H. Young, the medical officer of health for the district. The maps display even more strikingly the relation between these winds and the phthisis death-rates; the correspondence is remarkable. In this investigation there came out a definite though slighter effect of north-west wind upon the death-rates. Therefore in all subsequent work, this third clear rain-bearing wind of Devon, has also been taken into account.

The Third Test

It was now objected (unreasonably in view of other accepted work) that ten years was too short a period on which to found conclusions. So another specially suitable area, as regards contrasts of shelter and exposure, consisting of twenty-three parishes of the Exmoor part of Barnstaple Rural District, was examined over a period of forty-five years. In this work I have to thank my friend Dr. J. R. Harper, the district medical officer of health, for his invaluable help. Here once more the same law came plainly into view. Not only was the effect of exposure to north-west, west, and south-west winds upon female phthisis mortality evident for the whole period of forty-five years, but it was evident for every one of the nine successive five-yearly periods except the first. Further, during the twenty years 1885 to 1904, in which Koch's discovery of the tubercle bacillus must be held to have made the diagnosis more certain, the contrast in the death-rates between exposure and shelter became more marked, and in the decade 1890 to 1899 the death-rates presented a still more remarkable contrast. Finally, again to test even more severely the correspondence, maps were made showing the female phthisis death-rates between 1890 and 1899, and the relative parish exposures to south-west, west, and north-west winds. Again the correspondence was very striking.

These two last series of comparisons—namely, those in the rural districts of Barnstaple and Okehampton—have been the subject of the first independent inquiry into the correctness of my figures. Dr. John Brownlee in his able report to the Medical Research Council on the epidemiology of phthisis in Great Britain and Ireland (Part 3, 1920), re-examined the death-rates in the parishes of these two districts over a different series of years from mine, using a different method, and concluded that "it therefore appears probable that in these districts exposure to the south-west winds is associated quite definitely with an increased susceptibility to phthisis", adding "I think it must be admitted that Dr. Gordon has made out a very good case for further extensive detailed inquiry, and that he must be congratulated on the work which he has done". I need scarcely say that I only quote these remarks in full in order to make clear the extent of Dr. Brownlee's agreement. The subject is far too grave for egotistical triviality. It is noteworthy that, till a few weeks ago, this has been the only serious attempt made to verify my work.

The Fourth Test

One of the objections raised to my conclusions (if indeed erroneous explanation can be counted a objection) was that these winds only acted indirectly by compelling the closure of all doors and windows against them. Was it all doors and windows were only on the western sides of the house? So another investigation was devised. It it could be shown in a town, that the streets whose roadways were swept by these winds suffered most from phthisis, that would be some evidence that the effect is a *direct one on the people living* in those streets, since they must be regarded as the chief users of them and windows and doors need not be generally closed against wind which only blows past them. A report issued by the sanitary authority of Exeter afforded the opportunity of investigating this point.

It was then found that not only had the street of Exeter whose roadways were swept by the westerly winds about twice the female phthisis death-rate of the one which roadways were sheltered but that when the streets on different soils were separately considered the same contrast came out, the ratio being rather less than 2 to 1 on clay, rather more than 2 to 1 on sandstone, and more than 3 to 1 on gravel. Further, when the streets were divided into four classes according to their differing rateable values, in every class a ratio of about 2 to 1 was maintained. Lastly, when specially exposed roadways were compared with specially sheltered roadways (differences of soil being eliminated by only considering streets on clay, containing the most populous), the ratio for a second was 3 to 1

A World-wide Investigation

These four tests convinced me that, in Devonshire, populations exposed to prevalent strong rain-bearing winds suffer more from phthisis than populations sheltered from them. The next step was to see if the same law could be traced elsewhere. Now here it is necessary to say that the vast bulk of the available material abroad was not sufficiently reliable to support positive conclusions. But my search through many parts of the world was rather for *contradiction* than for confirmation of my other results. Such contradiction might have been very useful, I thought, in indicating fallacies undiscovered in Devonshire. *But there were actually no contradictions.* From every available part of the world confirmation came. As an interesting item I may mention that from the Sandwich Islands, which Hann says afford the finest example of a contrast between a wet and windy side and a dry and wind-sheltered side, Dr. Grace wrote to me that, in respect of phthisis, "the fact that the windward side is the bad side is well recognized here."

Bovine Tuberculosis

But the effect of these winds on tubercle is not confined to human phthisis. In 1910 Professor Delepine of Manchester read a valuable paper on the distribution of bovine tuberculosis amongst the farms supplying Manchester with milk. 1,524 farms, scattered over 5,000 square miles, were investigated and mapped, and these maps made possible an inquiry into the effect of westerly winds on bovine tubercle. Exactly the same relation became obvious, and when only evidently fully exposed farms were compared with evidently fully sheltered farms, the exposed were found to have about four times as much tuberculosis amongst the cattle as the sheltered.

So much for the influence of these winds on the incidence of phthisis. Now for their effect upon the fate of those who have contracted the disease.

Effect on Phthisis Patients

It might be reasonably surmised that the effect of these winds on phthisis patients would not be favourable. All the great phthisis health resorts which have been conspicuously successful have been situated in pronounced shelter from prevalent strong rain-bearing winds, and the comparative failure of English sanatoriums may be explained by the blind placing of them, on German advice, in all sorts of unsuitable conditions, too commonly in westerly wind exposed localities. But surmise is not enough. The matter is too serious.

Duration of Cases

Dr. Harper's figures afforded me in 1912 the opportunity of investigating the stated "durations" of female cases in shelter and exposure. He was good enough to have the recorded durations attached to his cases, and I divided these into three categories—namely, "long cases," lasting fifteen months or more, 'medium cases," lasting between ten and fourteen months, and "short cases," lasting nine months or less. The result was so suggestive that I proceeded at once to treat two other quite different areas similarly. Dr. Young kindly obtained the durations of the cases in the parishes of Okehampton district. Here I classified the durations somewhat differently. Then I examined the durations in the parishes about Budleigh Salterton, and obtained similar results.

All these three areas showed the same effect of the winds. In all three the exposed parishes had a higher proportion of "short cases" and a lower proportion of "long cases" than the sheltered parishes. It might have been objected that recorded durations of cases cannot be fully relied on. But to this it may be replied that it is very unlikely that the errors supposed would by mere chance tell in the same direction in the records from all three areas, also that there is, after all, no real ground for assuming the presence of such errors as would invalidate the results. Now, however, we can proceed to a much more incontrovertible mode of inquiry.

Effects on Early Cases

Thanks to the recent tuberculosis regulations, it is now easy to mark on the map the exact location of the dwellings of phthisis patients, and to follow their fortunes through a sufficient number of years. For the application of the new method which I am about to describe I am indebted to the great kindness of my friends, Dr. Adkins, medical officer of health for the County of Devon, and the tuberculosis officers for the county.

Method of the Following Inquiries

Let me explain precisely the plan on which we have proceeded. Lists were first drawn up of *early (Grade 1) cases of phthisis which had passed through a sanatorium* (in practically all cases Hawkmoor Sanatorium) *and had been observed individually for four years afterwards.* These cases have been classified as "male" and "female," "with tubercle bacilli found," and "without tubercle bacilli found", and at the end of four years as "dead," "arrested," and "living"—that is, not arrested. The exact position of the dwelling in each case during the four years has been marked by a dot on a Bartholomew's reduced survey coloured contour map (the well known touring map), and to each dot has been attached signs showing the class to which the case belongs, as well as its exposure to or shelter from all winds between N N W and S S W. The signs used have been M = male, F = female, + = tubercle bacilli present, − = tubercle bacilli not found, *D* = dead, A = arrested, L = living but not arrested, S = sheltered from all westerly winds, X = exposed to any or all of these winds.

As regards "shelter" and "exposure," I have found in long practice that 100 ft. of altitude shelters half a mile to the leeward of it well, and a further half mile faintly. Beyond a mile from the 100 ft. its shelter must be regarded as ceasing, and dwellings situated further off will be exposed. I am sure that the only satisfactory method of assessing "shelter" and "exposure" is by measurement on the map. No other method can be checked by outsiders. No other method is so free from fallacy. It is, moreover, the method which I have hitherto used in my work. Lastly, it makes an inquiry possible which would be utterly impossible to undertake by local investigation of sites.

In dealing with these new figures I think it may be prudent to lay most stress on the female cases, which have formed the basis of all my former work in Devon. For we know that the occupations of the women are more uniform than those of the men, and (what is even more important in this inquiry) these occupations keep the women mostly in the immediate vicinity of their dwellings, whereas those of the men not uncommonly take them into quite different localities.

Grade 1 Sanatorium Cases in Devon

The first figures which I shall show you are those from East Devon and from North Devon. The assessment of cases in South Devon has presented exceptional difficulty as regards shelter and exposure, and Dr. Ward has preferred to withdraw them for the present. The figures for East Devon were assessed jointly by Dr. Galbraith and myself. Those for North Devon were mostly assessed by Dr. Swan, my only notable interference being to insert two arrests in exposure, which we had overlooked—an interference by no means in the interests of what might be supposed to be my expectations.

TABLE I.—*East Devon*

Sanatorium Cases. First Stage. Four Years Observation.

	Exposed	Sheltered		Exposed	Sheltered
Dead			*Mortalities*		
Males	9 (7)	0	Males	56%	0
Females	3 (1)	2 (2)	Females	33%	7%
			All cases	48%	4%
Arrested			All T B cases	72%	13%
Males	0	7			
Females	3	22 (1)	*Arrests*		
			Males	0	29%
Living			Females	33%	81%
Males	7 (2)	17 (2)	All cases	12%	57%
Females	3 (1)	3 (1)	All T B cases	0	15%

TABLE II.—*North Devon*

Sanatorium Cases: First Stage. Four Years' Observation.

	Exposed.	Sheltered.		Exposed.	Sheltered.
Dead.			*Mortalities.*		
Males	11 (9)	0	Males	50%	0
Females	4 (2)	0	Females	30%	0
			All cases	44%	0
Arrested.			All T B cases	52%	0
Males	3 (2)	7 (2)			
Females	3 (2)	3 (1)	*Arrests.*		
			Males	14%	70%
Living.			Females	43%	60%
Males	7 (4)	3 (1)	All cases	17%	66%
Females	6 (2)	2	All T B cases	19%	50%

INDEPENDENT INQUIRIES

Grade 1 Sanatorium Cases in Other Counties

1 *West Shropshire.*—From Shropshire I have just received the results of the first independent inquiry made on these lines. Dr Watkin, one of the county of Shropshire tuberculosis officers, has most kindly investigated the West Shropshire area, as being the area affording the greatest contrasts in that county between shelter and exposure. It will be seen that his figures (Table III) fully confirm those which we have obtained in this county. Although, as he points out, the numbers of cases are small, I would emphasize the importance of this entirely independent confirmation.

TABLE III.—*West Shropshire*

Sanatorium Cases. First Stage. Four Years' Observation.

	Exposed.	Sheltered.		Exposed.	Sheltered.
Dead.			*Mortalities.*		
Males	9 (7)	1 (1)	Males	31%	8%
Females	7 (5)	1 (1)	Females	29%	14%
			All cases	30%	10.5%
Arrested.			All T B cases	54%	25%
Males	9 (1)	5 (1)			
Females	8 (1)	4	*Arrests.*		
			Males	31%	41%
Living.			Females	33%	57%
Males	11 (6)	6 (4)	All cases	32%	47%
Females	9 (2)	2 (1)	All T B cases	9%	12%

2 *Derbyshire.*—In Derbyshire it has been impossible to carry out the method in its entirety, but the medical superintendent of the county sanatorium has most kindly sent me the results of two years' observation of Grade 1 patients, dividing the county into three districts, distinguished by differences in their rainfall. Now rainfall *per se* has practically no effect on phthisis mortality. And a glance at the maps, which Dr Barwise, the medical officer of health for Derbyshire, has very kindly sent me, shows that the north-west area is pre-eminently the most exposed to wet winds. The table of mortalities is here again most instructive.

TABLE IV.—*County of Derby*

Sanatorium Cases. Male and Female. First Stage. Two Years' Observation. Discharged 1920. Condition 1922.

District.	Dead.	Arrested.	Living.	(Untraced.)
A *North-west District* (40-50 in. rain)				
Tubercle bacilli +	1	11	6	(9)
Tubercle bacilli −	1	10	3	(7)
B *Middle District* (30-40 in. rain)				
Tubercle bacilli +	0	3	0	(2)
Tubercle bacilli −	0	16	4	(7)
C *South-east District* (under 30 in. rain)				
Tubercle bacilli +	0	12	2	(10)
Tubercle bacilli −	0	40	13	(22)

Mortality of (all) Traced Cases (taking T B + and T B − together).—District A 6 per cent. District B 0. District C 0. Mortality of T B + cases in District A = 5 per cent.

I hope to receive later on the results from other counties which have also been good enough to undertake similar investigations.

PRINCIPLE OF "APPROXIMATE ISOLATION OF INFLUENCES"

In all further investigation of this subject I am sure it is essential to bear in mind the principle I have ventured to lay down, of the "approximate isolation of influences." Until Koch devised a means for the isolation of micro-organisms no precise work on bacteriology was possible. That was a complete isolation. The isolation of influences in climatology can only be approximate. But the additional precision given to results by such approximate isolation will be instantly realized by anyone who carries it out. By such approximate isolation I mean not merely the happy-go-lucky elimination of this or that influence in the investigation of a third, but the systematic enumeration of all the known influences which seem to affect the field of inquiry, besides the influence in question, and their successive elimination from the problem in one way or another, so far as that is possible. The process naturally is neither easy nor short. For illustrations of its use I must refer you to my former publications.

SOME MISAPPREHENSIONS

There are some misapprehensions still needing notice, because still causing confusion.

First, there are some people who imagine that my work in England concerns only the south-west wind. It concerns all westerly winds, which in England are the prevalent, strong, rain-bearing winds. In other parts of the world other winds are concerned. In Mid-Europe the predominant wet wind is the north-west. In South Europe the south-east has also to be taken into account. In all Europe, however, west and south-west winds must be always considered. In Japan the north-west is the main wet wind. In the tropics there are the Trades, which are easterly. *Everywhere the formula to remember is "prevalent, strong, rain-bearing wind."*

Again, Dr Haviland's work is still confused with mine. To Haviland is unquestionably due the credit of first perceiving that "wind" affects phthisis. But, so far from being a "follower of Haviland," I was fortunately quite unaware of his work until I found the fact on which I lay such stress. Haviland's statements were quite different from mine, and had I been familiar with them, it is not unlikely that I should have missed my point, as he did. Naturally when my own work brought me to hear of his I acquainted myself with it. The point I here insist on is not the always slightly absurd point of personal priority, but the vitally essential point of *difference*.

CONCLUSION

We have thus before us, ladies and gentlemen, a mass of diverse evidence, all clearly pointing to one and the same thing—a profound influence exerted upon phthisis by prevalent, strong, rain-bearing winds, affecting both its incidence and its course.

In respect of incidence no mere climatic factor has so powerful an effect (a fact whose further proofs would take too long to relate this afternoon) and amongst social factors only occupation equals it in importance. We may safely say that the chance of becoming phthisical is *at least twice as great in exposure to these winds as it is in shelter from them.*

As regards course, it may be fairly said that the chance of recovery is *at least twice as great in shelter from these winds as it is in exposure to them*, and that therefore *there is no detail of treatment more vitally important to the patient than the placing of him in effective shelter.*

In closing I would thank most cordially the Devonshire friends already named who have done so much with their encouragement and co-operation to make this story possible, also outside Devon Dr F. J. H. Coutts, senior medical officer to the Ministry of Health; Dr J. Wheatley, medical officer of health for Shropshire; and Dr S. Barwise, medical officer of health for Derbyshire, for the valued interest and assistance also Dr A. C. Watkin of the great trouble he has taken in West Shropshire to procure us his independent results and the medical superintendent of the Derbyshire Sanatorium for the figures he has sent me in spite of much pressure of work. To Dr John Brownlee, Director of Studies to the National Medical Research Committee, I would also express my deep indebtedness the subject owes much of his initiative and staff

The Bradshaw Lecture
ON THE
PREVENTION OF ACUTE RHEUMATISM.

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS, LONDON, NOVEMBER 4TH, 1924,
BY
F JOHN POYNTON, M D, F R C P LOND,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

THE prevention of acute rheumatism is faced with many difficulties, and I think the more closely it is studied the more apparent these become

1 The first of these difficulties is nomenclature, for acute rheumatism may be the most insidious of maladies Yet if we leave out "acute" and use the term "rheumatism" we are at once overwhelmed by the various disorders with which we are confronted, and if we abandon the term "rheumatism" altogether we shall have great difficulty in finding a substitute It is when the prevention of acute rheumatism is entertained upon a great scale that this weakness in the nomenclature becomes of practical importance

2 The next difficulty is concerned with the etiology of acute rheumatism considered as an infective disease This view of the causation has a most important bearing upon the possibilities of prevention, but is at present in a state of uncertainty When, in 1898, I first became associated with my faithful and valuable colleague Dr Alexander Paine, Dr Cheadle had already enunciated the clinical reasons for suspecting that acute rheumatism was due to some infective process At the moment the whole question is being reinvestigated, and I believe I shall not be wrong if I put the present position somewhat thus that many of those who have given the most attention to the subject recognize the importance of the strepto-diplococcus, but do not think that it affords a complete explanation of the etiology, and would look elsewhere for this—to some filter-passer, for example Neither do I look upon this micrococcus as a complete explanation, but I do not anticipate the discovery of another infective agent I look for help from the unravelling of the tangled skein of the secondary factors which combine with the micrococcus to produce this specific disease Until the solution is revealed I feel, with the utmost respect for my able opponents, that I have caught something of the spirit which inspired Giordano Bruno to reply to the sentence of his inquisitors "Majori forsitan cum timore in me sententiam dicitis quam ego accipiam"

3 In any case, even if we admit that acute rheumatism is due to a specific infection, we find ourselves confronted by further problems, among which are the many factors predisposing to the infection—such as heredity, environment, and nerve strain

4 Again, our conception of the disease is still deficient in two particular directions we have very little accurate knowledge either of the life-history of such an infection when once it has gained access to the human frame, or of the influence of the tissue characteristics and habits of the patient upon its course On this account I have always connected with any scheme for the prevention of acute rheumatism the provision in such for opportunities for research

5 The varied symptoms of the disease dependent upon the various important organs attacked constitute yet another difficulty, though one which must steadily diminish with increasing knowledge, and which will be met by careful medical instruction and by the gradual education of the public

6 Then there is the difficulty of treating this disease with success, and upon this point, so far as children are concerned, I unfortunately find myself at variance with many able physicians Except for the relief of pain, my experience as to sodium salicylate and other members of that group has been so unsatisfactory that I have no hesitation in stating that in the most formidable cases of carditis in the young my best results have been obtained without their use Until, then, some new remedy is discovered or some additional assistance to these drugs I feel that we have little direct control over the course of acute rheumatism

Reasons for Attempting Prevention

It may be asked whether it is not premature, in the face of so many difficulties, to enter upon elaborate attempts at prevention, but to this I believe we may safely answer "No," and for these reasons It is generally admitted that acute rheumatism is a cause of three disorders of national importance first and foremost, organic heart disease, secondly, chorea, and thirdly, arthritis and fibrositis It is not a rare disease but a frequent one, and the heart lesions, chorea, and arthritis are common manifestations It is much more rife in the poorer classes, and this can only mean that hidden in the complex problem of poverty are some of the important factors in the determination of the incidence of the disease, and the study of poverty with a view to its amelioration is undoubtedly a function of a civilized country Again, it is a disease which certainly responds to careful supervision and treatment, and there are at the present time flaws in our supervision capable of at least considerable mending Lastly, it is not a disease of the old and failing, which would be, I admit, a sufficient evil, but it is one that kills and maims children and young adults, damages useful citizenship, and wastes much money spent on education This is well illustrated in an inquiry by Dr H A Chadwick into the nature of 140 fatal cases of acquired heart disease in children all under 12 years of age In 89 the heart disease was rheumatic, whereas the next in order of frequency, the pneumococcic, numbered only 27

A recent Blue Book on the subject of the "Incidence of rheumatic diseases" in its quiet pages supports all the statements I have just made This Blue Book I have heard criticized in a way which I can perhaps best express by likening it to one of those strange dishes which appear at intervals in schools, and which is supposed to contain the odd fragments left from many and various meals covered in, not by blue paper, but by a pie crust For my part I have no criticism to make, but look upon it as a document of first importance, for it brings home two essential truths The first, the great national importance of rheumatism The second, the formidable difficulties that confront us in dealing with the problem, for I am convinced that when efforts for the prevention of acute rheumatism are made upon a large scale, those concerned more closely with the aspect of investigation will certainly find themselves perplexed as to where the lines are to be clearly drawn between the various forms of "rheumatism" This Blue Book does great service in pointing out the morass of "rheumatism," and it remains for investigators to make paths through this sufficiently broad and safe to enable the medical profession and public to see how far attempts at prevention can be made sane and practical Any scheme to be successful must appeal to the public as well as the medical profession as a reasonable proposition

The Medical Practitioner

In the prevention of acute rheumatism it is clear that the doctor in general practice must, as in all the great problems of preventive medicine, take a prominent and essential part—not only in early diagnosis and treatment, but in the supervision of those who have suffered from the results of the disease To these further activities I will allude later on in this lecture, but it is not too much to say that if this branch of our profession failed us—which is not thinkable—the whole fabric of prevention would be unsound at its foundations The responsibility for adequate training in the clinical and pathological aspects of the disease rests with the great teaching centres To them we must look for rousing in the minds of future practitioners an enthusiasm for the great opportunities they would have for helping to make a success of a scheme which holds out such great possibilities

The Hospitals

Our hospitals, and in particular the children's hospitals and the children's departments in the general ones, would in any scheme hold, I presume, the same position they do now, in that they would receive the acute cases and any which required particular observation or investigation They would also carry out the training of the undergraduate students in the recognition of the disease and its manifestations, and the methods of prevention and immediate treatment The notes of the cases, which will often be concerned with first attacks, should clearly become of great value for future reference and of increasing importance in any large undertaking for prevention The out patient departments of hospitals would be mainly consultative They would in the poorer cases take the place of the general practitioner as supervisor, but their most essential functions would lie in deciding a difficult diagnosis, in admitting to the hospital, and advising doctors and patients as to the best procedures at the moment Experience shows me that it is not satisfactory to bring many of these delicate children by train, tram, and tube, to wait about in hospitals during the winter and early spring months The parents, too are placed in a difficult position, for they naturally cannot exactly judge whether such a child is fit to travel and yet fear to lose their appointment at the hospital A system, too, which converts a hospital physician into a human turnstile to aid hospital grants is intrinsically unsound

We are now met by a weak point in our management It is common knowledge that recovery from acute rheumatism is often slow, and that neither cardiac inflammation nor chorea is a condition suited to ordinary convalescent homes These children are notoriously unstable the rheumatic infection admittedly treacherous, and to group them with strong children recovering from surgical injuries a passing debility, or a rapid pneumonia, so unsatisfactory that physicians are well aware of the dangers The alternatives are to keep them in a sick ward in the middle of a great town, or to send them home

When hospitals fulfil the intentions of their philanthropic benefactors, in treating the children of the necessitous poor, many must be sent back to entirely wrong surroundings The weakness, then, in the present position is twofold we are not doing the best for our rheumatic patients and we are using beds in expensive institutions which are required for urgent or obscure cases

Recovery Hospitals

Each year it is becoming more evident that the great cities and London in particular require *recovery hospitals* in the adjacent country in vital touch with the mother hospitals Should public opinion in the future favour a step in this direction you will appreciate that two alternatives arise either such hospitals will be *special* and in this case devoted to the rheumatic, or be *general* with a special section for the rheumatic I favour the latter but would naturally accept the former as a step in advance of the present position

In an ideal hospital of this type the cases would have the necessary time for convalescence would, in the surrounding grounds be trained for physical exertion and eventually classified according to their ultimate degree of recovery and they would also—a point of great importance—continue their education The history of acute rheumatism would be continued as a sequel to the first hospital notes, and eventually the children returned to their parents with a short practical statement as to their capabilities

There would be one link in this chain which must require the most careful consideration for it is essential There must be an *intimate and vital connexion between the* parent and recovery hospital If the latter once drift into a second rate soulless abode for 'uninteresting cases" its value is lost and it becomes a monument of inefficiency This danger when once realized can certainly be prevented by organization if our profession so determine

Pioneer attempts have already been made in this country —as, for example, at the Edgar Lee Home (Stonebridge Park), Broadstairs at the Chiene Hospital, in Birmingham and at Bristol, and doubtless elsewhere The Invalid Children's Aid Association in particular has taken a prominent part in this movement and has recently started a home of fifty beds for females up to 14 years and males to 7 years of age at Hartfield in Sussex I have the honour to be one of the honorary visiting officers and though it is too soon to make a report on progress for we have not been through a winter I may remark that at present the results are encouraging The gains in weight, the absence of attacks of rheumatism, the improved physique, and happiness of the children who are continuing their education and living and sleeping practically in the open air, make me hopeful that we are entering upon a real advance in the treatment of rheumatic heart disease To those who have given their time and skill in these pioneer *efforts I feel deeply grateful*

Official Medical Supervision

Leaving now the part played by hospitals I come to the far reaching activities of the Ministry of Health Board of Education, and medical officers in the London County Council schools Hidden away in their not superficially attractive reports there are some of the most fascinating chapters in modern medicine, which leads me to confess that I have hardly done justice to my colleagues in these great departments—a lapse which I take this opportunity to correct

Infant Welfare

There is already, as you are well aware considerable medical supervision in this country During the first year of life we have the infant welfare centre from 5 to 14 years the school medical officers and from 16 years onwards the national insurance There are two breaks in complete continuity—one between the second and fifth years and the other between the fourteenth and sixteenth years The break between the second and fifth years—which in theory does not exist but in practice does—will doubtless eventually be bridged and already encroached upon on the one side by the infant welfare organization and on the other by the school authorities

I have given considerable time and attention to the subject of acute rheumatism under 5 years of age, and, though I am not implying that the disease is frequent then, I am sure that it occur more often than is generally suspected, and that it is liable in these early years to cause great damage to the heart Supervision between 2 and 5 years should eventually throw light on the earliest phases of the disease

School Medical Service

The period of school life is by far the most important in the history of acute rheumatism in this country The incidence of the disease rises rapidly after the fifth year to about the tenth, and chorea which I have seen as early as 9 months, and occasionally in the second year comes now to the front It follows that the school medical service must take an ever-increasing share in the problem of prevention This becomes apparent if we study a report of the chief medical officer devoted to heart disease and rheumatism in 1912 In this we are at once impressed by the vast number of children dealt with the importance or organic heart disease as a factor of ill health and by the frequency of acute rheumatism as its cause Already there the importance of prevention is realized as also the following two or cases the need for precaution on return to school and the possibilities of residential school

The appearance of chorea during the school age demand I think special attention I shall not delay with statistics showing that it is a rheumatic manifestation I have myself made four analyses each from a different source which convince me of the essential truth This manifestation is most interesting one for on account of the peculiar movements it becomes the most sensitive clinical index we have of active rheumatism it is also the manifestation which most frequently occur alone and has a most striking evidence Accordingly we find of the course of chorea gives as a very fair indication of the

general behaviour of acute rheumatism, thus we see acute attacks which terminate rapidly, and we see cases which linger on for some months and are continually recurring As many as six attacks may be recorded in a few years, and some children between attacks are never quite free from the effects and may be thought mentally deficient We recognize two elements—the infective and the nervous There is no doubt that nervous tissue is slow in recovering from its injury even after an active infection has been destroyed, but when we recall that repeated chorea is a frequent indication of an early mitral stenosis, we suspect that both these lesions are pre-eminently the result of the *smouldering activity* of infection

I see in chorea the danger of a great national system of education framed by adults for delicate, sensitive rheumatic children Do not suppose that I am hinting at harshness or cruelty on the part of the teachers—that I dismiss at once, but the process of education begins very young, and the routine is a strain upon constitutions of which we may truly say "the spirit indeed is willing, but the flesh is weak" The rheumatic child is bright and eager, but cannot last the course, for she is lacking in stamina Routine on the one hand and a constitution that requires frequent rests on the other must clash, and not infrequently does—for example, over scholarships I believe there is a gradual lowering in general vitality, and then the infection attacks first the nervous system, which is the most strained, and often also the heart and other organs

For my part, seeing the frequency of chorea in London children (9 per cent of the out-of-school children in 1923), I would not leave one stone unturned until either, on the one hand, I proved that the view I held was a bogy, and that other causes to account for its frequency must be discovered, or that, if it was mainly correct, steps were taken to analyse the exact nature of the educational strain

There is a passage in the report of the chief medical officer of the Board of Education which deserves particular attention It comes from a report in 1923 of the consultative committee on the differentiation of the curricula for boys and girls respectively in secondary schools This committee draws attention to the present danger to health connected with the strain of examinations and of accomplishments added to the boys' curricula, and they note the relatively heavy household duties devolving at this age on many girls I see in this passage light for the future and a sense of the reality of things, which cheers me almost as much as the sight of a flowering shrub upon the walls of one of those gaunt buildings with which we are so familiar

Early Adolescence

Still keeping our attention to the official side of the medical problems, we come now to the age of early adolescence—14 to 16 years—and to the time when the child leaves the supervision of the school medical officer and has the choice of occupation immediately ahead Everyone recognizes that this is a critical period in life, and it is unfortunate that just at this time there is a break in the continuity of official supervision The school medical officer is left and the national insurance has not begun I am not in a position, nor have I the time, to enter into details of the difficulties surrounding this gap, but will try to indicate the present position

The inspections of the school medical officer are concerned with three groups of children the "entrants" to the school, those between 7 and 8 years, and lastly, the "leavers" The leavers' examination may take place one or two years before leaving, and there is often available medical information extending over nine years of school life These histories are strictly confidential, but they are available for the use of juvenile employment bureaux, who are concerned with placing in employment children who leave at 14 years Again, in the case of children continuing their scholastic career in schools for higher education and children suffering from severe physical defects up to 16 years, the school medical service is available, but as you are aware the number of such children is very limited

Factory Surgeons

We come now to the factory surgeons, some of whom are school medical officers and all of whom are encouraged by Sir George Newman to co-operate closely with those officers These examine adolescents of 16 years entering factory life, and those under that age who enter employment, including certain specified workshops, which requires an earlier training When, however, we consider the problem of the London children we find many enter occupations which do not require a certificate of fitness This is a weak link in the chain, and perhaps the more apparent because some three years ago the gap between 14 and 16 years was practically closed by the day continuation schools The axe, however, fell, cutting through this slender neck, and the young head of the school medical period tumbled into the basket of economy

The report of the Departmental Committee issued this year shows, moreover, that the Factory Act has not proved satisfactory In 1920 it was found that nearly 8,000 individuals were rejected in the United Kingdom by the factory surgeons on medical grounds, and 576 of these for diseases of the heart and lungs This clearly points to some leakage in the period between leaving school and applying for factory employment We must bear in mind that this Act does not require co-operation between the school medical service and their reports and the local authorities and their reports on the one hand, and the factory surgeons on the other Valuable suggestions for strengthening this weak link have been made by the Committee, which from my point of view are also links in the prevention of acute rheumatism The phase of that problem which is mostly affected by such improvements will concern individuals who have already had attacks of rheumatism and have probably some damage to their heart, for, though first attacks occur between 14 and 16 years of age, it is the recurrences that are more frequent I should, perhaps, at this point say that I include in the prevention of acute rheumatism the sequelae, because I believe at present no *practical line* can be drawn between active infection *and improper strain* thrown upon a damaged organ In children, certainly, some active infection is usually the secret of most cardiac breakdowns

We see from this short outline of the official side of the medical problem that one of its most important duties is akin to that of the signalmen on our railway lines—at certain stages along the line of life these officials indicate danger and pull up the train The medical practitioners and hospitals clear the track and endeavour to prevent further breakdowns

Works' Doctors

There is another link, and one of increasing value, in the chain of prevention This is the appointment by many large industrial concerns of special medical officers, matrons, and nurses, to supervise the health of their staffs There cannot be any doubt that this link, forged though it may be on the anvil of strict business by the hammer of self-defence, must do great good, particularly when that service is fair seeing and kindly If we are to prevent acute rheumatism and minimize its dangers it is essential, especially for the young, that we should be able to come to their assistance quickly and not allow them to drift on until they are brought by grave illness to a standstill The very existence of such a medical service, in touch with capital on the one side and labour on the other, must eventually help greatly in the development of any scheme for prevention

The General Practitioners

As I have already stated, throughout early life the doctor in general practice is taking an unobtrusive yet important part in attending rheumatic children, but, as Dr Carey Coombs has suggested, they could offer more special assistance by the formation of voluntary groups in various districts around some great city In this way some point under investigation in the city hospital, such as the incidence of the disease in certain areas or the appearance of a local epidemic, would enable them to use their special knowledge and experience We must remember that limitations of time necessarily make the great store of clinical experience in this branch of our profession difficult to call upon, but this

suggestion by Dr Coombs would, I am sure, give them this opportunity and be most helpful in extending our accurate knowledge When the insurance age is reached, and indeed in every stage of life, the general practitioners who give time, opportunity, and interest to this particular subject can continue to furnish valuable data not to be otherwise obtained The British Medical Association, alive to the importance of the problem, which was brought before it in 1923 in a valuable discussion opened by Dr R Miller, has already taken steps to lend assistance in advancing our general knowledge

Increased Co operation

I must here make a short digression to touch upon a somewhat delicate subject, on account of which my remarks must be looked upon as an expression of a purely personal view

Taking a broad outlook there are three great medical forces in this country the hospitals, with a magnificent history of past and present work, but financially unstable, the Ministry of Health, young and powerful, with immense resources and advantages, and the general practitioners, with the all-important assets of experience of the dawn of disease and intimate acquaintance with their patients Each can take a most valuable part in the prevention of acute rheumatism, but greater results are to be expected if these forces can be drawn closer together Greater organization between them would, in my opinion, enhance the value of the school medical service, which appears to me often to be in the position of a doctor whose patient has been under a consultant's care and returned to him without a note of guidance Looking to the future for one of these forces I can only see one fate, and this is that the hospitals become the strong right arm of the Ministry of Health I use the word "strong" advisedly, for to be strong there must be wide liberty of thought and action, and not the suffocating growth of "officialism"

This digression is not intended to be controversial, but has, I think, a distinct bearing on the subject of this lecture For my part, I should like to see skilled officers, somewhat on the lines of our hospital medical registrars, but representatives of the Ministry of Health, linking up the cases and notes of the rheumatic patients in our hospitals with those of the school medical officers, and bringing to us hospital physicians the particular lines of thought and investigation under the consideration of the Ministry, and in turn keeping the latter in intimate touch with hospital activities In another direction also there are great possibilities and that is in the co-operation of hospitals and almoners with the Board of Education and their army of voluntary workers and the Child Care Committees The importance of this co-operation is, I believe, appreciated at some of our hospitals and should be of particular value, and these organizers, by bringing the activities of the hospitals into touch with the outer world of medical service, could widen the horizon of the student and indeed of all of us From the standpoint of the rheumatic children they would give great assistance in following up these cases when they leave the hospitals and keeping in closer touch with them At the Hospital for Sick Children already I have had valuable continuation histories and home details of my rheumatic cases supplied by this agency In the common aim at the prevention of acute rheumatism I see a good opportunity to bring the three great medical forces in this country closer together, and in this direction further possibilities for prevention

Environment

The influence of environment upon the incidence of acute rheumatism is one of the problems in prevention which appears to me particularly to need more extensive investigation This aspect is one which I always associate with the honoured name of Sir A Newsholme, who showed us the importance of urban life as a factor in causation My personal experience of this side of the problem is not an effectual one, because my activities have been confined to technical research and clinical study in hospitals but I have noticed these points Damp and cold houses and districts tend to make acute rheumatism drift into a chronic course, and it is my belief that a child returning from hospital after an attack, to such surroundings is certainly in great danger of chronic invalidism and likely to die in a few years Whether or not this is the entire explanation I am convinced that there are houses which are most injurious to such children, this is based on my knowledge of healthy families coming to such houses and several members developing acute rheumatism, which also recurred when they returned after convalescence I am also most suspicious of cold winds when there has been a spell of hot weather and much dust in the towns, this combination producing tonsillitis and increasing the incidence of acute rheumatism. The medical officers of health would have a prominent part in this investigation, and already to my knowledge they are taking the problem in hand, and the Care Committees should prove invaluable

Notification

Here the question arises as to notification, and it seems to me that a suggestion I have heard is worthy of consideration It is that a partial and temporary notification might be helpful General notification in the present state of our knowledge would probably lead only to great expense and confusion It might, however, be advisable to notify acute heart disease in childhood, or chorea, or obvious cases of acute rheumatism up to a certain age and for a limited time, and I understand that the medical officers of health would thereby be put in a stronger position Personally, I am not sure that notification is needful or for the best, and leave it as an open question

Contagion is an aspect which at present I should not care to be brought into prominence, believing that it does not take an important part in the history of acute rheumatism An epidemic of sore throat in a household predisposed to the disease might result in several members developing active symptoms, and I have met with cases in these circumstances sleeping in the same bed, one of whom developed cardiac rheumatism, the other chorea, but these are very exceptional events There are occasionally outbreaks in strictly limited areas, and in 1919-20 around and in London there was a distinct wave of increase of incidence This feature is one which certainly requires more study, but I think it would be premature to bring contagion to the fore in any public movement

Education of the Public

Two directions suggest themselves by which we can better instruct the public the first, by educational leaflets and lectures to bring home to parents, patients, teachers and labour employers the dangers of the disease, and the second, to assist them in choosing industrial occupations and in recognizing the limitations of employees who have been partially maimed by acute rheumatism

The Ministry of Health could, I believe, render a great service if it would publish a leaflet for the guidance of the public, setting out in simple terms the dangers of acute rheumatism, together with some simple instructions These could be sent to hospitals to medical services to great factories, and wherever from its special experience it would think helpful I have ventured myself to outline such a leaflet and I know it has been of some value, but this would be better done by those more experienced in the practical needs of the public In the other direction—the assistance of the public in the problem of employment—we require the best possible organization for providing information for the guidance of those who have rheumatic children to place in life Schedules of suitable employments should be easily obtainable, and there is no doubt that in the future the deeper study of employment in relation to acute rheumatism and cardiac disabilities will give us much useful information At present the school medical officers do valuable advisory work on these lines, but more can probably be done to gain the assistance and sympathy of employers It certainly should become increasingly difficult for such a case to occur as recently came under my care This was an undersized girl of 20 years with obvious mitral stenosis who was working as a bottle labeller, underground, often in wet clothes and lifting heavy cases As a result she was admitted with a complete cardiac breakdown from which she has never recovered

The Local Focus

The next point is the removal of local focal infection as a factor in prevention On June 7th, 1900, a man, age 28, came to St Mary's Hospital suffering from a sore throat The condition was one of acute tonsillitis and he had mitral and aortic disease, arthritis, and muscular pains There was a previous attack of rheumatic fever four years before Dr Paine, by plate culture, isolated a streptococcus morphologically and culturally indistinguishable from that we had isolated from the lesions of acute rheumatism Intravenous injections into a rabbit produced acute aortic and mitral endocarditis Fitz-Meyer, two years later, by extensive experiments supported these results, and later with Mr George Waugh we repeatedly verified the ability of this micrococcus obtained from unhealthy tonsils to produce cardiac and arthritic lesions without any previous injury to the valves This was the birth of the local focus in rheumatism

No one can be *more* convinced than I am that the rheumatic infection has one important site of entry into the system through diseased tonsils, and particularly those which resemble, in their deep recesses, culture tubes No one probably is *less* convinced than I that wholesale removal is indicated in the rheumatic child, or that the removal of the local focus shuts the door Nature is not so easily managed, and I have seen severe carditis in a first attack occurring some years after a complete enucleation Recent American statistics bear out this experience, for Ingerman and Wilson report that, of a series of cases in which tonsillectomy had been undertaken for rheumatic manifestations there occurred, in a period between one and eleven years after the operation, rheumatic relapses in 76 per cent I look upon the tonsils as an important barrier, but as no man is more dangerous than a clever man who has lost his capacity, so are badly damaged tonsils a constant source of danger Careful treatment of the throat, nasopharynx, and teeth in the prevention of acute rheumatism will be, in my opinion, a permanent factor More investigation is required to determine other local foci as equally definite

Research

That further research is essential to advance the prevention of acute rheumatism is generally admitted, and this must mean the assistance of expert investigators trained in the modern methods of bacteriology, serology, and biochemistry Opinions as to the best method for obtaining results will naturally differ, and I can but express my own views I think there should be some institution in which the study of "rheumatism" should be continued uninterruptedly, and in a centre such as London I would have this institution concerned with the entire problem of rheumatic affections, for it is my experience that in research one is liable, if following a particular line, to reach a dead end, some fact or some technical detail is lacking or the brain becomes wearied Then one needs to leave that line for a time and to work in other directions, returning later refreshed with new ideas or with new equipment The problem of "rheumatism" would always have open spaces, now there might be fresh light thrown on malignant endocarditis, now a discovery in the bacteriology of rheumatoid arthritis, or some chemical advance bearing upon fibrositis Thus the vitality of the research would be kept active

I am no believer in an easy path A keen intelligence even working on wrong lines will learn useful lessons and be the stronger, but one value in the establishment of a continuous research lies in the diminution of the likelihood that a young investigator would wander off the track for a long time If I may give one personal illustration—Dr Paine and I spent two years searching for a suspected bacillus and discarded the very micrococcus we eventually believed to be the causal agent of acute rheumatism Two years is a long time, and wiser heads might have given us a hint that would have put us right earlier in this vain search Such an institution could be organized for training investigators and putting them in touch with our great hospitals and infirmaries, and would have at hand an ample literature I admit the scheme is ambitious, but I am looking ahead and outlining what appears to me the rational steps to bring about a steady progress in our knowledge, remembering always the great wastage of money that present results from the ravages of rheumatism

Conclusion

I think that I have shown that we have in this country at least the skeleton of a valuable organization for the prevention of acute rheumatism Given the *will* to clothe this skeleton with living flesh, there seems to me to be great possibilities Dr Carey Coombs very wisely points out that any scheme must be evolved slowly, and I am in entire agreement with him It is my belief that the best results in most great endeavours are obtained by testing the strength and weakness of the materials already at hand rather than by wholesale revolution I have attempted to disclose weak points, and these can be cautiously strengthened No one would suppose that I should advocate filling the land with country hospitals, but *one* such connected with the children's hospitals in London would be an experiment justified by our knowledge of disease, and in this hospital acute rheumatism could form one section, and the results be carefully tested

Of this I am convinced, that Sir George Newman and his powerful staffs will continue on their side to develop our resources for prevention, and the hospital staffs and practitioners are prepared to take their parts It is for an enlightened public to consider whether they will help also, for it is for them and for their children that we are working If we are met by the answer that there is no money *for such* endeavours, then we can but improve to the *best of our* ability, and by mutual organization, our present resources, but the public should realize how many children and adults in this country are maimed by this disease, and should know our difficulties, our need for research, and the present limitations of our resources

In conclusion I would venture to repeat a prophecy I dared to give in 1913 in an address to the Invalid Children's Aid Association "That as surely as *I stood on* the platform the time would come when the care of *the* rheumatic child would attract much more attention in this country", and I would add now "in all civilized countries" I wish also in this lecture room, where the great name of Harvey has been so often glorified, to express my belief that the experimental production of organic heart affections by micrococci obtained from rheumatic carditis has opened up the road for a great advance in the treatment of cardiac disease and for the relief of much suffering, by leading our thoughts to the problem of the *prevention* of acute rheumatism

SPIROCHAETOSIS ICTEROHAEMORRHAGICA.

The Presence of the Causal Organism in Slime as a Source of an Outbreak in East Lothian

BY

GEORGE BUCHANAN, M.B., Ch.B. Edin., D.P.H.,

Assistant Clinical Pathologist, Royal Infirmary, and University Assistant, Edinburgh

(From the Research Laboratory of the Royal College of Physicians, Edinburgh)

A preliminary note[1] recording the occurrence of this disease in Scotland was published in February, 1924 Since that time an extensive investigation has been in progress, and is still being continued

At present it is desired to give an account of one aspect of the inquiry which led to the discovery of leptospiral organisms in a natural habitat hitherto unrecorded This observation will no doubt be confirmed in other circumstances which are being investigated, but the existing conditions associated with the present finding alone may help to throw further light on the epidemiology of the disease, particularly in relation to its occurrence in certain coal mines

In 1914 Inada and Ido discovered the causal organism of Weil's disease They reported their discovery in a Japanese journal in 1915 An English communication by Inada *et al.*, Hoki, Kaneko, and Ito,[2] which summarized the publications

in the Japanese literature on this subject, appeared in 1916 The disease was found to prevail in epidemic and endemic form in certain parts of Japan In addition to the liability of butchers, cooks, and field workers to the disease in that country, they noted its frequency among coal miners working in that part of a mine inundated with water They also stated that 'the spirochaetae seem to live in water and mud, and to invade the human body from there" A later communication by Ido and his associates announced the finding of the specific organism in a certain proportion of rats caught on the surface and in infected pits

Since the discovery of the causal organism the disease has been more widely recognized, and infected rats have invariably been considered one of the chief sources of infection in man Toyama' later observed that the prevalence of Weil's disease was closely associated with conditions of the soil in Japan, and found that all infected districts were paddy fields and localities with swamps ground Other observers have reported the presence of leptospiral organisms in water and mud, but the direct relationship of such water leptospiras to Weil's disease was not definitely established by animal experiment

Nature and Result of the Investigation

In the infected area in Scotland a considerable percentage of rats and field mice was found to be infected with the pathogenic spirochaete, or leptospira (Noguchi) This fact having been established, the examination of surface and pit waters was indicated This has been done on an extensive scale

A personal visit to one of the infected coal mines was arranged by the county medical officer of health for East Lothian, Dr G A Richardson, who, by the kindness of the pit owner, received permission for an inspection in February of this year It so happened that the mine visited was inundated with water in certain parts and was known as a "wet" pit A large number of water samples was collected, by means of sterile glassware, from different sections of the mine These samples included specimens from new cuttings where the miners were working practically under water from recent workings which were very wet and from old sections which may be termed damp in comparison with the other parts It was in one of the old sections that the following observations were made which resulted in a finding of much significance

Compared with other branches of the mine there was little ground water no water was seen to drop from the roof but the whole tunnel was very damp Small stagnant muddy pools were present from which samples were collected Roof water was looked for in vain, but on holding a lamp close to the tunnel roof I noticed a slimy viscid substance, which formed a small thin layer only in certain areas At parts it was seen to form hanging drops, which as they increased in size would no doubt fall into water or on to the ground Other portions of the roof in the same section were merely damp with no slime, while in certain areas red sandstone drippings were present The viscid substance was certainly not plentiful, and even the small amount collected was found only after careful search

Wet films of the slime were first examined by dark-ground illumination, which revealed remarkable and varied forms of motile organisms, in addition to primitive forms of the vegetable kingdom Different types of spirochaetes were distinguished by their morphology and motility Only after prolonged examination were definite lepto spiral organisms found but they were few in number The difficulty in recognizing this delicate organism in such a viscid substance may be emphasized

To control the observation if possible, two guinea pigs were inoculated intraperitoneally with 2 c.cm of the glutinous material thinned by the addition of a little saline to permit of its passage through a syringe needle The result of these experiments was negative in both cases, no spirochetosis developed during one month' observation

A fresh sample of the roof slime from the same section of the mine was obtained at a later date Dark ground examination again showed the undoubted presence of typical leptospiras Two guinea pigs were again inoculated but on this occasion with 4 c.cm of the substance, as the failure to infect the first two was attributed to the scarcity of the lepto pira in the smaller amount injected Both animals died one on the eleventh the other on the third month day after inoculation They showed equally pronounced evidence of spirochetal jaundice Abundant leptospiral organisms were present in all the organs examined, and an appreciable number were also found in the blood and urine Notable features were the intensity of the jaundice the prominence of the widespread subcutaneous muscular, and internal haemorrhages the enlargement of the spleen, and the haemorrhage in the stomach in both animals In fact, the lesions appeared more pronounced than in guinea animal infected with the human or rat strains

It would appear, as far as can be ascertained from the relevant literature consulted that this is the first occasion on which the direct inoculation of a water lepto pira has proved pathogenic to guinea pigs This infected roof slime was found growing on slaty stone and wooden roof bar in absolute darkness It was greyish brown in colour, and translucent when free from carbon particles It formed a mass of considerable coherence and was not very readily detached from the stone roof The consistency approached that of a thick gum solution and resembled the semi solid culture medium of Noguchi used in growing lepto pira The temperature of the slime in the mine was 11 7° C in February It was slightly alkaline when tested with litmus paper and had a reaction of $pH=7.5$ approximately

As mentioned above, the lepto pira was recognized with difficulty in this substance teeming with other active life A few of them were much longer than those found in man the rat or in culture Other types of spirochaete were much more numerous particularly one species The characteristic motility of the lepto pira in contrast to that of the other spirochaetes present was striking and formed a feature which distinguished them from forms closely resembling the genus Most of the other spirochaetes on escaping from the slime were actively translatory and moved rapidly in a horizontal plane whereas the true leptospira remained in the field actively rotating for a second or two, then finally burrowed vertically into the viscid medium out of sight The lepto pira was found to exist in this semi solid medium symbiotically with algae, fungi, cocci, bacilli pirochaetes, flagellates, nematodes, and their ova This slimy substance was formed by organisms with a glutinous envelope which yielded a jelly like or zoogloea mass

The continued existence of the lepto pira and the other motile organisms was noted at different temperatures Some tubes of slime were kept at room temperature, and others in the ice chest for over five months Dark ground examination at the end of that time showed all the motile organisms, including lepto piras quite recognizable and unimpaired in their activities Animal inoculation were recently done to determine if the slime after keeping had maintained its infectivity The results are not yet ready for publication

It was previously noted that the slime was observed only in a very damp and old section of the mine its situation on the roof appeared inaccessible to rats I was informed by the pit manager that at the time of the outbreak of jaundice in May 1923 practically all the miners affected were working in a particular section This section was stated to have been the wettest part of the mine Of much significance becomes the fact that this particular section happened to be that branch of the mine in which the infected roof slime was found Eight miners developed symptoms of spirochaetal jaundice when employed in the mine in question Five of these were said to have fallen ill within a period of two weeks while working in this very wet cutting Rats were never considered numerous in the pit, and an expert rat-catcher failed to trap any underground for examination but caught one on the surface This rat was found to be infected with pathogenic leptospira

Discussion

It is highly probable that such lepto pira as were present in the mine may enter by various routes A fall of cutting into a new wet section exposing lime in the soil

above may be dislodged by the force of movement of the ground water escaping into the pit. Miners locally, therefore, may be more exposed to infection at that time. After the flow of inrushing ground water has diminished, the soil above is less likely to be disturbed. At a later period elements of slime in water, oozing from the soil, may settle and grow on the roof to form a nidus for the growth of the leptospira and other organisms. This slime may possibly drop on to the ground, into stagnant pools, and running pit water, from which sources man and rat alike, locally and at a distance, may conceivably become infected. It may be, however, that the pathogenic leptospira escaping from this rich natural organic medium into running water, or water with little organic matter, becomes attenuated after residence in the less favourable environment, as do the human and rat strains in culture medium. There will be a wider distribution of the organism in infected water than in the slime; therefore dosage may be an important factor in infection. Conditions in the mine which may possibly influence the pathogenicity of the leptospira are darkness, temperature, and depth. The temperature of the slime in the mine was 3° C. higher than that of pumped water in a cement surface pond. No cases of jaundice appeared to be associated with either the pond or in adjacent stream into which the pond water flowed. These waters both showed the presence of certain spirochaetes, but no leptospiras were found in the centrifugalized deposits. Animal experiments with these and other surface waters have so far given negative results.

The opinion stated above, that the absence of favourable and adequate organic matter in the water may be a factor in the attenuation of a pathogenic leptospira, receives support at the time of writing. In an English version of Toyama's work[5] just published it is recorded that a pathogenic strain actually became attenuated in experimental ponds with no soil, but preserved its virulence for a longer period in ponds with soil. Moreover, it is stated that "the spirochaete could preserve its poisonous nature two months in an imitation paddy field, which had entirely no self-cleaning function." The organic properties of the soil and water in which the leptospira may exist as a pathogen would therefore seem to be a factor in the preservation of its virulence. That the presence of the associated organisms in the slime and soil may lower the resistance of man and experimental animals, and so act as aggressins, requires consideration, as advised by Dr. P. P. Ludlow. A French writer inoculated large doses of impure cultures of a water leptospira into guinea-pigs with negative results.

Spirochaetes, now considered similar to the genus Leptospira by Noguchi, were observed in water by Wolbach and Binger[6] in 1914. They reported the isolation of a filtrable spirochaete from the shore of a fresh-water pond near Boston. Its pathogenicity for experimental animals was not tested. Several observers since then have recorded the occurrence of the same genus in water. Zuelzer,[7] in 1922, discovered in tap water spirochaetes which morphologically resembled those of Weil's disease. Direct inoculation of the naturally infected water into animals, however, did not give rise to any symptoms. One strain of a water leptospira proved pathogenic to guinea-pigs after cultivation in serum medium for one and a quarter years—that is, mutation from saprophyte to pathogen had apparently occurred. Stevenson (unpublished observation) found a leptospiral organism in London tap water, but no guinea-pig inoculations were carried out. Rats injected with the water gave negative results. Both fresh and salt water have been found by Noguchi[8] to contain leptospiras indistinguishable from those producing disease in man. The organisms did not prove to be pathogenic to guinea-pigs.

Small epidemics of spirochaetal jaundice occurred last autumn in Northern France, one of which was associated with the river Vesle, at Reims. A number of young people who bathed in the river contracted the disease. Etchegoin[9] examined the water and mud of the Vesle, and found a leptospiral organism which he considered had slightly wider elementary spirals than *Leptospira icterohaemorrhagiae*. The river water and mud, and massive doses of impure cultures of leptospira, were tested by animal inoculation, but did not produce spirochaetal jaundice.

It would thus seem that leptospiral organisms exist as saprophytes in certain waters and mud. The saprophyte and pathogenic forms are stated by most observers to be morphologically indistinguishable. Their close relationship in other directions has been demonstrated by Uhlenhuth and Zuelzer.[10] Mention of mutation from saprophyte to pathogen has already been made. Biological and immunological tests carried out by them support the view of the water origin of Weil's disease. On the other hand, Akira Shiga[11] recently recorded serological differences between certain water strains and *Leptospira icterohaemorrhagiae*. The latter is stated to thrive in the immune serums of the former, but not in its own immune serum. The two different races of water leptospira tested were likewise only affected by their homologous immune serum, both being uninfluenced by the immune serum of the pathogenic strain. They also proved the greater power of resistance of the water organisms to ultra-violet rays and other influences, but found no great difference in the behaviour of the saprophytic and pathogenic strains towards certain parasiticides.

It has not been possible so far to carry out comparative serological and certain other tests with the slime, rat, and human strains in the present investigation. The most important property of pathogenicity, however, has been proved by animal experiment to be common to the three strains. Natural habitats of the genus have been found in wet soil and in water. It remains to determine if varying natural environments alone can influence mutation from a pathogenic to a saprophytic type and vice versa, or if immutable species exist. The change from a virulent to an avirulent organism in altered natural conditions was suspected, and the view held finds confirmation in Toyama's work already quoted. No mention is made of a return of virulence on introducing the water attenuated leptospira into wet soil again. In the outbreak investigated by the writer it was observed that no cases were associated with the surface pond or stream, both of which received pumped water, presumably containing some leptospiras, from the infected pit. The pond was lined with cement, contained little soil, and the temperature was 8° C.—factors possibly favouring attenuation. The stream was said to receive boiling water from mines near its banks. On the other hand, the change from saprophyte to pathogen in natural conditions has not been determined. A water saprophyte, however, was reported by Uhlenhuth and Zuelzer to have acquired pathogenic properties in culture medium.

The localization of the disease has been generally recognized, in spite of the presence of leptospiral organisms in many waters and rats in districts where the disease has not occurred. Epidemics have invariably been associated with wet and badly drained broken ground, as in stanced by outbreaks among workers in rice fields and wet mines. During the war epidemics among soldiers were localized more or less to wet, ill drained trench. The disease has also occurred among workers in sewers. In such environments conditions no doubt exist for the development of slime similar to that found in the mine. This slime medium apparently affords an ideal nidus for the growth and aggregation of pathogenic leptospira. Apart from environment such as favourable wet soil and slime, the organism may become attenuated as mentioned above, which suggests a possible reason for the localization of the disease.

Swimming baths in the poorer quarters of Paris have been held responsible for recent outbreaks, and certain bathing pools in Germany have been incriminated. It may be that leptospiras, attenuated by sojourn in water, borne from soil, gain entrance to the ponds along with primitive vegetable elements capable of forming a zoogloea mass as a nidus. In this organic medium exaltation of virulence may possibly occur. One instance has been referred to in which a saprophytic water leptospira became pathogenic.

It is highly probable that rats inhabiting wet mines originally become infected from broken soil. They may acquire infection by feeding on slime in old disused tunnels blocked up with loose stones, as seen in the mine visited. One rat was actually observed to scamper into this ideal

hiding place These old damp inaccessible branches no doubt afford favourable situations for the collection of much slime the development of which will probably depend on the nature of the soil above One means of combating the rat source of infection may perhaps be accomplished by completely walling off such conceivable breeding grounds from the main roadway

Rats far distant from infected mines in East Lothian were also found to be infected with the leptospira but no cases of jaundice have been reported in the particular areas Fouleiton,[1] Balfour,[13] and Stevenson[14] recorded the presence of pathogenic leptospiras in rats from different counties in England where the disease was unknown Coles,[15] at Bournemouth, noted the existence of infected rats there but pathogenicity tests were not done The findings suggest that the leptospira is more ubiquitous in soil than at present suspected and that rats may harbour a food deficiency in infected slime in soil It may be also that they can acquire infection from water attenuated leptospiras which, by passage, become pathogenic to man in certain circumstances

Reasonable evidence for the assumption that rats become infected from slime soil, or water, and so act as secondary disseminators of the disease was found on examination of their urine In addition to the presence of leptospiras, similar spirochaetes to those found in the slime and certain waters were found in the urine of many rats by dark-ground illumination

Summary

The discovery of an unrecorded natural habitat of the causal organism of spirochaetal jaundice has been reported

The natural habitat was found in an infected coal mine, and consisted of root slime formed by organisms with a glutinous envelope which yielded a jelly like or zoogloea mass

Inoculation of the slime in guinea pigs produced pronounced and fatal spirochaetal jaundice

The viscid slime proved to be a favourable medium for the growth and continued life of the leptospira which lived symbiotically with many other species of organisms

The observation has established a possible source of infection underground, where the leptospira existed in a situation inaccessible to rats

I desire to thank the Committee of the Royal College of Physicians Laboratory for the facilities afforded me to carry out this research

The Medical Research Council has defrayed the expenses of this work and given valuable assistance in other directions
